ACKNOWLEDGEMENTS

The Ecological (Biophysical) Land Classification of Banff and Jasper was conducted jointly by the following agencies:

Environment Canada
- -Canadian Forestry Service, Northern Forest Research Centre, Edmonton
- -Canadian Wildlife Service, Banff, Jasper and Edmonton

Agriculture Canada
- -Alberta Pedology Unit, Land Resource Research Institute, Edmonton and Ottawa

Alberta Institute of Pedology
- -located at the University of Alberta, Edmonton.

Major funding was provided by Parks Canada. Assistance provided by the Western Region Office, Parks Canada, Calgary is acknowledged, in particular: P.A. Benson, D.L. Day, J.C. Holroyd, K.E. Seel, and C. Zinkan.

The authors also express their appreciation for the cooperation and assistance of A.S. Anderson, D.A. Dumpleton, R.T. Flanagan, R.J. Haney, P.A. Lange, D.J. Martin, T.L. Ross, J.T. Steele, P. Whyte, E.B. Wilson, T.R. Wilson, D.J. Woodrow, and to all the wardens in both parks.

Thanks go to the following for assistance in plant identification: G.W. Argus, M. Barkworth, I. Brodo, N.H. Holmgren, D.G. Horton, G.A. Mulligan, M. Ostafichuk, J.G. Packer, T. Reeves, J.W. Thomson and D.H. Vitt.

Special recognition is extended to R.E. Wells and S. Kojima for their contributions to the land classification in its earlier stages, and to B.J. Berteau, H. Dudynsky and S. Dupuis for their contributions to computer data management and report production.

W.C. McKean and A. Schwartzer conducted soil laboratory analyses. The complete list of field and office assistance, including students, is in Volume II.

The early contributions of the Canadian Wildlife Service were made by J. Stelfox and D. Karasiuk. The assistance of the Canadian Wildlife Service, including G. Scotter, E. Telfer, M. Robertson and administrative staff is acknowledged with thanks. Later contributors are acknowledged in Volume III.

Excellent service was provided by helicopter pilots J. Davies, G. Forman and K. Ostertag.

The Land Resource Research Institute contributed in two ways. First, in the drafting of the 24 maps by B. Edwards and the Cartography Section and secondly, in assisting in the development of the data bank through the services of the Canada Soil Information System (CanSIS).

The assistance of the Canadian Forestry Service, including G.T. Silver, R.W. Reid, and administrative staff, is acknowledged. Special thanks must go to W. Chow and N. Leenders for computer services, to P. Debnam for photographic assistance, and to the stenographic pool.

ABSTRACT

Banff and Jasper National Parks occupy about 17,520 km² (6765 mi²) in Canada's southern Rocky Mountains. The area extends from approximately 53° 30′ N and 119° 30′ W at the northwest corner of Jasper to about 50° 40′ N and 115° 20′ W at the southern extremity of Banff. It is bounded on the west by the Continental Divide. The Ecological (Biophysical) Land Classification of Banff and Jasper presents landform and soil, vegetation and wildlife information in a map and descriptive format at a scale of 1:50,000 using a legend that integrates the resource components in a holistic fashion. A three-level, hierarchical land classification system was developed using established landform and soil taxonomies, plus a classification of 85 vegetation types developed by the authors. The three levels are based on existing guidelines for Ecological (Biophysical) Land Classification in Canada and include, from highest to lowest level of generalization, Ecoregion, Ecosection, and Ecosite.

Ecoregion separations are based primarily on vegetation physiognomy and species composition which reflect macroclimate. Montane, Subalpine, and Alpine Ecoregions are recognized. The Subalpine Ecoregion is subdivided into Lower Subalpine and Upper Subalpine portions based on vegetational characteristics reflecting macroclimatic differences.

The Ecoregions are divided into 55 Ecosections. Ecosection separations are based on broad landform, drainage class, and soil differences. Landforms are comprised of ten genetic materials that have been divided into twenty genetic material units based on broad textural and chemical (calcareousness/reaction) differences.

The Ecosections are further separated into 124 Ecosites based on specific soil and vegetational differences that are considered insufficient, in magnitude or kind, to warrant separation at the Ecosection level. The Ecosites, plus eight Miscellaneous Landscapes, are the mapping units delineated on 1:50,000 maps. Wildlife information is presented at the Ecosite level. The importance of each Ecosite for most of the large and medium size mammals is described. Eighteen breeding bird associations and seven small mammal associations are defined using multivariate statistics. The association and its relative abundance are listed for each Ecosite. The landform, soil, vegetation, and wildlife of each Ecosite are briefly described in this volume.

PREFACE

Parks Canada requested assistance to meet a number of objectives of the National Parks Inventory Program. The request indicated a need for knowledge of the kinds and distribution of landforms, soils, vegetation, and wildlife. Such baseline information, plus the elucidation of some basic ecological relationships among these natural resource components, is primarily for resource management and land use planning within the National Parks.

Parks Canada initiated an Ecological (Biophysical) Land classification of Banff and Jasper National Parks (Fig. 1) in May 1974 as part of their resource inventory program. The objective was to provide an integrated landform, soil, vegetation, and wildlife inventory of the two parks at a scale of 1:50,000 with data presented in map and report format. The field work was completed in 1980.

The Ecological (Biophysical) Land Classification of Banff and Jasper studied the geomorphology, soils, vegetation, and wildlife of these two parks, exclusive of cultural features and land use patterns present as a result of development since 1885. Though aware of cultural features, land use patterns, and land use conflicts within the two parks, the inventory team followed the terms of reference established by Day et al. (1975). The concept of natural resource studies and their advantages and deficiencies were also described by McTaggart-Cowan (1977). However, most of the land in the parks is not intensively used. Byrne (1968), Scace (1968, 1970), and Nelson (1970) present much of the history and development that has affected Banff National Park. Further sources of information are contained in the three volume bibliography by Scace (1973).

The complete Banff-Jasper report consists of three volumes plus a map supplement and contains generalized and detailed descriptions of the landform, soil, vegetation, and wildlife resources.

Volume I is a summary account of landforms, soils, vegetation, and wildlife.

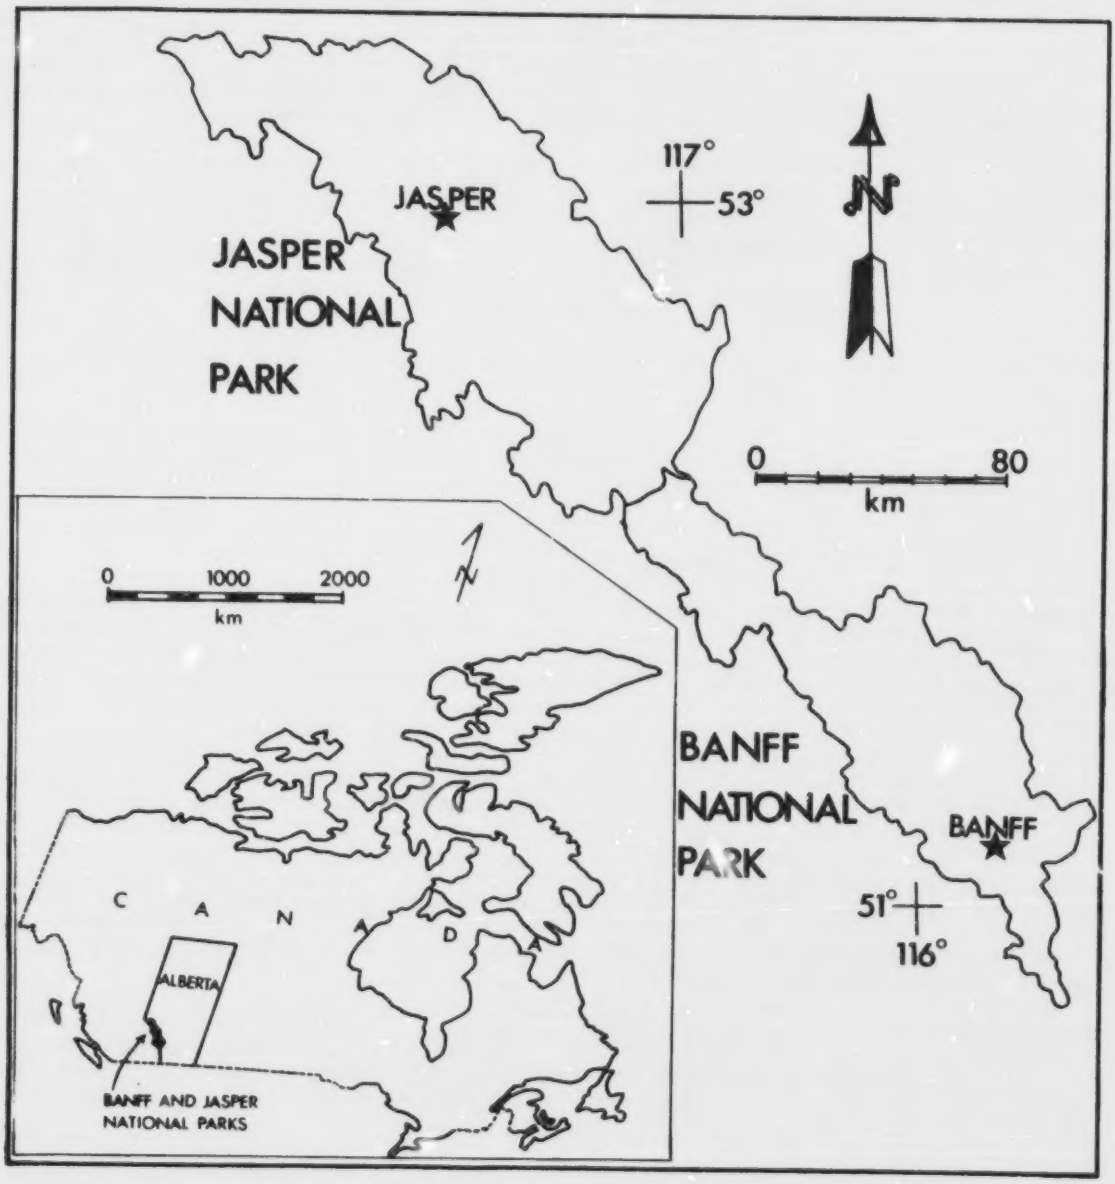
Chapter I of this volume contains the methodologies used both in the collection and processing of basic data andin the development of an integrated, holistic ecological land classfication system. Chapter II describes the study area in general. Chapter III provides Ecosection/Ecosite descriptions summarized from Volumes II and III and includes comments on management considerations. Chapter IV concerns resource use interpretation. It provides information on interpretive classification to help resource managers make land use suitability decisions.

Volume II contains a detailed account of the landforms, soils and vegetation. It describes the physical environment, including climate, physiography, topography, geology and geomorphology. The soil orders encountered and their distribution are also outlined. The vegetation information describes 85 vegetation types (v.t.s), a key to v.t. identification, an overview of community succession, special and significant species, and a checklist of vascular and nonvascular plants. The main body of Volume II provides an ecological integration of landforms, soils, and vegetation into three Ecoregions, 55 Ecosections and 124 Ecosites. An encyclopedic style was adopted to allow readers to consult the report on the subject of immediate interest without necessarily reading it from the beginning.

Volume III reports on the wildlife portion of the inventory. It contains a detailed discussion of the occurrence and abundance of each species of herptile, bird and mammal. Included are habitat preferences and notes on life history and management considerations specific to each species. The discussion of wildlife occurence on each Ecosite in Volume I is summarized from Volume III.

Other sections in Volume III describe breeding bird communities, small mammal associations, bird migration, ungulate range surveys, wildlife distribution by watershed, and various recommendations.

Fig. 1. Location of study area



The fourth part of the report is a map supplement, containing 24 maps (scale 1:50,000) and the Master Legend. The maps depict the distribution of Ecosites and Miscellaneous Landscapes. The Master Legend contains abbreviated information on the landform, soils, vegetation and wildlife of each Ecosite.

To obtain the most complete information, all report components should be used together. In addition, users should be aware that the information in this report is scale dependent. Site specific management decisions require site inspection and ground-truthing of the Ecosite data. Users may find it useful to consult with the authors regarding valid use of the information.

Copies of the original annotated air photos are filed with the Resources Studies Manager, Western Regional Office, Parks Canada, Calgary. Most basic data are stored in the Canada Soil Information System (CanSIS), Land Resource Research Institute, Ottawa.

ECOLOGICAL (BIOPHYSICAL) LAND CLASSIFICATION METHODS

PHILOSOPHICAL PRINCIPLES GOVERNING DEVELOPMENT OF THE ECOLOGICAL CLASSIFICATION METHODOLOGY

Experience has shown that for ease of use, all resource sectors should be linked to one set of map polygons of appropriate scale (1:50,000 was chosen for Banff-Jasper, Day et al. 1975) and the map legend should describe holistic, repeating ecological map unit concepts.

Three guidelines were used to develop the mapping procedure for Banff and Jasper:
1. Map, legend, and report should be easily interpretable.
2. Map unit concepts should be repetitive and holistic.
3. Map information should be uniform in reliability and intensity.

These guidelines were addressed by choosing a semi-closed legend and simple map symbol encompassing a holistic, ecological concept of landform, soils, and vegetation. Only the slope and, occasionally, selected landscape modifying processes were allowed to vary somewhat independently of the concept as applied to map polygons. This choice allowed the development of an ecological map unit concept (Jurdant et al. 1975, Rowe 1979), limited the number of concepts, permitted legend interpretation followed by mechanical labeling of repetitive map polygons, and included many factors in an easily remembered symbol. It also allows transfer of experience from a familiar area to an unfamiliar, but similarly labeled, area without reference to the many specific landscape components such as texture or lime.

Map delineations were chosen to correspond with recognizable landscape (usually landform) features because soil and vegetation often change where landforms change and reliable extrapolation from aerial photographs is possible. The smallest practical map polygon at scale 1:50,000 is 0.5 to 1 cm^2 and represents a tract of 25 to 40 ha (50 to 100 acres).

The legend in this study is hierarchical, but the mapping is not. That is, while initial landscape stratification established Ecoregion, Ecoregion subunit, and genetic material unit boundaries (Plates 82, 83, 84, Vol. II), in the final mapping polygons were named at the Ecosite level and modified by slope class. Thus, land is not cartographically stratified into polygons representing the Ecosection or Ecoregion however, therefore the aggregate that is Ecosection exists conceptually and therefore the legend is hierarchical.

MAPPING METHODOLOGY

METHODOLOGY OF LEGEND DEVELOPMENT

No nationally acceptable taxonomic system for ecological classification exists. There are useful guidelines (Lacate 1969, Jurdant et al. 1975, Wiken 1980) for developing classification

procedures. A vegetation "community type" taxonomy was developed for Banff and Jasper and combined with existing landform and soil taxonomies into a legend that defines the mapping units. This was accomplished through a series of annual legend, vegetation taxonomy, and mapping refinements following field checking of pretyped areas. Field teams consisted of one soil and one vegetation scientist, each recording information at a mutally acceptable, representative point on the landscape. Wildlife data collected the following season were also incorporated into this iterative process and resulted in further refinement of the Ecosite concept.

DESIGN OF THE MAPPING LEGEND

The mapping legend was developed with limits separating mapping concepts coincident with probable taxon limits where possible. The following discussion of Ecoregions, Ecosections, and Ecosites shows how these taxonomic levels influenced the mapping legend.

ECOREGIONS

Three Ecoregions are represented in Banff and Jasper: Montane, Subalpine, and Alpine. Separation was based on differences in vegetation physiognomy and species composition that reflect differences in macroclimate.

ECOSECTIONS

Ecoregions were divided into 55 Ecosections, based on broad genetic material and drainage class differences. These were named after geographic features and assigned a two letter, connotative symbol.

Genetic material classes that resulted in the establishment of Ecosections are listed in Table 1. These eight groupings were subdivided into two moisture regimes: *wet terrain* with soils classed as poorly drained and very poorly drained (C.S.S.C. 1978b) and *non-wet terrain* with soils classed as moderately well drained and drier. Imperfectly drained areas were variously considered wet or non-wet depending on their spatial and conceptual associates.

Wet terrain was not further subdivided. Non-wet terrain was subdivided on one or more of the following criteria where appropriate in occurrence, extent, or homogeneity:

1. Calcareous versus noncalcareous genetic materials.
2. Three genetic material textural groups, specifically coarse with >60% sand (sand, loamy sand, part of sandy loam), medium (loam, silt loam, part of sandy loam) and fine (clay loam, silty clay loam, silty clay textural classes). Textural classes are as defined by C.S.S.C. (1978a).
3. Soil-vegetation classes reflecting geomorphic activity or mesoclimate within a Genetic Material Unit (Table 8).
4. Landform surface expression producing a cartographically inseparable dry>wet landscape pattern.

Table 2 shows, as an example, organization of Lower Subalpine Ecosections associated with glacial genetic materials.

ECOSITES

The 55 Ecosections were further separated into 124 Ecosites on the basis of vegetation physiognomic and floristic differences as well as differences in soil parameters. They were named as numerical subdivisions of the Ecosection name. Subdivision into Ecosites was based on the following criteria where appropriate in occurrence, extent, or homogeneity:

1. Vegetation physiognomic groupings (closed forest, open forest, shrub, low shrub and herb, herb).
2. Habitat grouping (poplar forest, lodgepole pine forest, lodgepole pine/buffaloberry forest, Engelmann spruce-subalpine fir forest, a mosaic near timberline of heath tundra plus scattered Engelmann spruce-subalpine fir trees or krummholz, subalpine larch forest, avalanche complex vegetation).
3. Genetically similar soil or landform parameters (imperfectly drained soils, moderately

well drained and drier soils, or Brunisolic soils, Brunisolic–Regosolic soils, and Brunisolic–Podzolic soils, or ice contact stratified material and morainal material).

4. Complex Map Units (cartographically inseparable soil and vegetation patterns controlled by northerly and southerly aspect, dry and wet terrain, varying soil parent material depths over bedrock).

Table 3 gives an example of the subdivision of an Ecosection into its component Ecosites.

METHODS OF SOIL DESCRIPTION AND ANALYSIS

Pedon and site information as suggested by Day et al. (1975) was recorded on computer coding forms using the procedures and guidelines of Dumanski et al. (1975) and C.S.S.C. (1978 a,b). The soil, site, and vegetation data were sorted and organized by computer as an aid to developing and refining the mapping legend.

FIELD EXAMINATION AND SOIL DESCRIPTION METHODS

Ground checking was carried out after initial landscape stratification on aerial photographs to refine polygon boundary locations and to corroborate interpretation of landform, soil, and vegetation. Observation sites were located and annotated on the aerial photographs. Various pedons were chosen to represent soils of each Ecosite after ground checking and mapping procedures were completed. These pedons were described in detail on CanSIS forms and sampled for routine laboratory analysis.

† **Vegetation** In order to differentiate PR1 from PR2, vegetation is presented at a more detailed level of description than for the other PR Ecosites.

CHEMICAL AND PHYSICAL ANALYTICAL METHODS

LABORATORY ANALYSIS

Chemical and physical analyses were carried out after the samples were air dried and ground according to the routine procedures used by the Alberta Institute of Pedology (C.S.S.C. 1978c). These involved a determination of:

Soil Reaction: pH was determined with a pH meter using a 2:1 0.01 M $CaCl_2$ solution to soil ratio (Peech 1965).[3.11][1]

Total Nitrogen: determined by the macro Kjeldahl–Wilforth–Gunning method (A.O.A.C. 1955). A mixture of HgO, $CuSO_4$, and K_2SO_4 (Kelpak) was used as a catalyst.

Calcium Carbonate Equivalent: inorganic carbon manometric method of Bascombe (1961).

Organic Carbon: by difference between total carbon and inorganic carbon. Total carbon was determined by dry combustion using an induction furnace (Allison et al. 1965) with a gasimetric detection of evolved CO_2 (Leco model 577–100). [3.611]

Cation Exchange Capacity: by displacement of ammonium with sodium chloride (Chapman 1965) except that an ammonium ion electrode was used to detect the displaced ammonium ion. [3.321]

Exchangeable Cations: extraction by Neutral N NH_4OAC (A.O.A.C 1955) with K, Mg, Na, and Ca determined by atomic absorption spectroscopy. [3.53, 3.531]

Sodium Pyrophosphate Extractable Iron and Aluminum: by McKeague (1967) method. The determination of Fe and Al was done by atomic absorption spectroscopy. [3.53,3.531]

Particle Size Distribution: by the pipette method of Kilmer and Alexander (1949) as modified by Toogood and Peters (1953), except that carbonates were not removed prior to dispersion.

Liquid Limit, Plastic Limit, and Plasticity Index: by the method outlined by ASTM (1970). [2.61, 2.62, 2.63]

One-third and Fifteen Bar Moisture: by the pressure plate and pressure membrane methods (U.S. Salinity Laboratory Staff 1954). [2.44]

Bulk Density: by the soil clod method using Saran (C.S.S.C. 1978c) The samples were oven dried and weighed. Calculations were based on air dry volume. Values reported are the arithmetic mean of 3 to 5 determinations per horizon. [2.221]

FIELD TESTS

Percolation: by the method suggested by the Alberta Department of Manpower and Labour (1972). This consists of digging a hole to the depth of interest followed by saturation for 24 hours before measuring the rate of drop of the water level in the hole.

Infiltration: by the double ring method with a constant head apparatus as suggested by Adams et al. (1957).

---

[1]The numbers in [] indicate the method in C.S.S.C. (1978c).

METHODS OF VEGETATION DESCRIPTION AND ANALYSIS

FIELD SAMPLING

Since a prime objective of the vegetation study was to provide information for the Ecological Land Classification, the methods were subject to the constraints of a 1:50,000 mapping program. Polygons of homogeneous composition were initially outlined on air photos. Single sample plots were then established in homogeneous areas representative of the predominant vegetation of selected polygons. Plots were generally 20 x 20 m in forested vegetation, 15 x 15 m in shrubby vegetation and 10 x 10 m in herbaceous and dwarf shrub vegetation. Smaller plots (5 x 5 m or 1 x 1 m) were sometimes necessary to keep plot boundaries within a homogeneous area, as in some intricately patterned Alpine areas.

Within each plot, canopy cover was estimated to the nearest percent both for individual species and for each layer. Epiphyte cover was not estimated; species were merely noted as being present. Five layers were recognized: 1) Tree layer: woody plants >5 m tall, 2) Tall Shrub layer: woody plants 2 to 5 m tall, 3) Low Shrub layer: woody plants 0.5 to 2 m tall, 4) Herb-Dwarf Shrub layer: woody plants <0.5 m tall and all herbs regardless of height, and 5) Bryoid layer: terrestrial lichens and bryophytes. Cover values were also estimated for ground litter, rocks and stones, mineral soil, deadfall, and water. Usually, one of the largest trees in the plot was measured for height and diameter at breast height (dbh) and cored to determine its age. Average tree canopy height and the mean and range of dbh were also estimated.

Physical environmental factors noted included: elevation, slope, aspect, topographic position, relief shape, landform, soil subgroup and drainage class. Each plot was also rated on a moisture regime scale (Table 4).

Table 4. Ecological moisture regime classes (Walmsley et al. 1980).

Class	Usual Soil Drainage
xeric - very dry, little precipitation or high evapotranspiration, very low available water storage capacity (AWSC)	very rapid
subxeric - dry, low AWSC	rapid
mesic - moist, intermediate to high AWSC	well to moderately well
subhygric - moist to wet, variable AWSC, seasonal seepage	imperfect
hygric - wet, variable AWSC, permanent seepage	poor
subhydric - wet, variable AWSC, excess water most of time	very poor
hydric - very wet, standing water constantly	

VEGETATION CLASSIFICATION

The vegetation was initially classified into five physiognomic classes: Closed Forest (C), Open Forest (O), Shrub (S), Low Shrub–Herb (L), and Herb–Dwarf Shrub (H). In Closed Forests, the distance between tree crowns is no more than twice the mean crown diameter. This generally corresponds to a lower tree cover limit of 15 to 20%. In Open Forests, the distance between crowns is 2X to 5X the mean crown diameter and tree cover is generally between 5% and 15 to 20%. Vegetation with <5% tree cover was not considered forested. Within these physiognomic classes the classification was based primarily on the dominant species in each layer and on characteristic combinations of species. Dominance or importance was determined by cover values and thus, the classification has a quantitative basis. The plots were grouped on the basis of shared characteristics into abstract units called vegetation types (v.t.s). The v.t. is of the same order of magnitude as the "association" of the Zurich–Montpellier approach (Westhoff and van der Maarel 1973) or the "biogeocoenose" of Sukachev (Sukachev and Dylis 1964), although the bases and methods of recognition differ. Both seral and climax v.t.s were recognized. The species used to name the v.t.s were usually layer dominants. A hyphen (–) separates species in the same layer; a virgule (/) separates layers.

METHODS OF WILDLIFE DESCRIPTION AND ANALYSIS

SAMPLING RATIONALE

A wide variety of methods was chosen to collect data on the seasonal abundance, distribution and habitat characteristics of all species of mammals, birds, amphibians and reptiles that occur in Banff and Jasper National Parks. The broad scope of the inventory and the large area necessitated a variety of approaches to data collection. The sampling methods were fast, simple and quantitative. Some methods were directed specifically at relating wildlife abundance to the ecological land classification and these are described here. Other methods were used to survey the seasonal movements of selected species, to determine the densities of some species, and to locate less common wildlife species. These methods are detailed in Volume III.

Four methods were used to relate wildlife occurrence to each Ecosite. The main considerations in selecting these methods were:

1. Each sample area must be small enough to fit entirely within one map polygon. The maximum area sampled was 500 m x 500 m.
2. Each method must require minimal time, effort or equipment and allow a limited number of staff to sample a large number of sites over a wide area of rugged terrain.
3. Each method must be quantitative and easily taught to new staff.

The techniques selected were pellet group counts with forage use plots, track count transects, call count transects and snap traplines.

DESCRIPTION OF METHODS

Breeding bird populations were sampled by counting birds along 500 m transects before 9:00 a.m. between June 1 and July 15. The number of birds recorded was corrected for detectibility (Emlen 1971) and density indices were calculated for all transects on each Ecosite. Cluster analyses were used to identify bird communities which were then related to each Ecosite. Red squirrel numbers were also assessed using this method.

The relative abundance of small mammals on each Ecosite was determined using traplines of 100 *Woodstream Museum Special* traps baited for two nights. The number of rodents and shrews that were caught was averaged for each Ecosite. The averages were used in a cluster analysis to identify associations of small mammals.

The relative importance of each Ecosite to each ungulate species was determined by counting pellet groups. Each count was conducted over 25 quadrats (2 m x 5 m) spaced 50 m apart in 5 rows of 5 quadrats each. The number of pellet groups of each species was multiplied by 40 to

give the number of pellet groups per km² and the average density was calculated for each Ecosite and vegetation type. The number of snowshoe hare pellets was counted in each corner 0.5 m x 0.5 m of each quadrat. These counts were multiplied by 400 to yield the density of hare pellets per km². On some pellet group sample sites the vegetation was also surveyed. At these sites, the abundance of the six most common plants was noted in each quadrat and use of any plants was recorded as a percentage of the plants eaten. The results were tallied for all quadrats on each Ecosite and vegetation type. This information was used to identify major forage plants on each Ecosite and to partially explain the importance of an Ecosite to ungulates.

Winter mammal activity was assessed by counting the number of tracks intercepted by a straight transect of 0.5 km or longer. Track counts were standardized to the mean number of tracks per 10km-day by dividing the total track count by the total distance of the transects and the number of days since the last snowfall. These figures were averaged for each Ecosite and vegetation type. Snow depth measurements were made on most transects. In addition, all birds seen or heard were recorded.

ECOLOGICAL INTEGRATION ANALYSIS

The above four methods were the primary sampling techniques for relating the abundance of wildlife to each Ecosite and vegetation type. The numerical values derived from each method are not presented here. Instead, the values were ranked in numerical order and rated as follows: the lowest third were rated as Low, the second third as Medium, the top third as High, and the top 5-8% as Very High. These ratings were then assigned to the corresponding Ecosites. Separate ratings were derived for each carnivore and ungulate species, since the range of values for each species varied greatly depending on the species' abundance and the degree to which it occurred in groups. For small mammals and breeding birds, rating schemes were developed for species groups. This was because of the large number of species involved and the lack of species-specific management in the national parks.

Thus, for each species or species group, the importance of an Ecosite is considered to be directly comparable to the measured relative abundance of that species on an Ecosite. Critical habitats are the highly and very highly ranked Ecosites and vegetation types, in addition to habitats with special functions (e.g. denning, calving or staging). It is important to note that some critical areas may be site-specific and not predictable by habitat designation. Thus, random observations and site visits should be included in any site-specific analysis of wildlife.

An additional method of ranking Ecosites was devised for lynx, coyotes, wolves and cougars since relatively few tracks of these species were recorded. From other studies of their food habits, a ranking scheme was created based on the importance of each Ecosite to their prey species weighted by the proportion of the prey in each predator's diet. For further details see Volume III.

In this volume the importance of each Ecosite to wildlife is briefly discussed. Generally, only the species for which the Ecosite is highly or very highly important are identified. Factors that result in the importance rating, such as snow depth, forage abundance and prey availability are discussed briefly. In addition, for ungulates and carnivores, a single rating of importance is presented for each Ecosite. This rating is derived from the sum of the individual species ratings. It is not intended to be used for site specific planning or management but for planning at the park level or larger.

LOCATION AND PHYSIOGRAPHY

INTRODUCTION

Banff and Jasper are situated within the Continental Ranges of the Southern Rocky Mountains, part of the Eastern System of the Cordilleran region of Canada (Bostock 1970). The parks form a crude northwest-southeast trending parallelogram that extends 425 km from about 53°30' N and 119°30' W to 50°40' N and 115°20' W. The approximate area of Jasper is 10,880 km², while Banff is 6,640 km².

Physiographic features of Banff and Jasper are strongly controlled by structure of the Front and Main Ranges geologic subprovinces. Both they and their features trend in the same direction mentioned above. The Front Ranges typically have steeply dipping strata that produce linear ridges of resistant rock separated by subparallel valleys carved from softer rock. Bedrock dips steeply southwest, providing long, smooth slopes on this aspect and precipitous cliffs on northeast aspects. The Main Ranges strata, for the most part gently dipping, produce nonlinear ranges with high individual or clustered peaks capped by resistant rock.

Peak elevations generally increase from east to west and are highest in the vicinity of the Columbia Icefield, reaching over 3700 meters. The lowest elevation, 990 meters, occurs where the Athabasca River exits Jasper.

DRAINAGE AND HYDROLOGY

Banff and Jasper abut the Continental Divide and are part of the headwaters for the Peace, Athabasca, and Saskatchewan River Systems. The mountains comprise about one-eighth of the drainage area but supply about seven-eighths of the total annual flow of the Saskatchewan River System. In the parks, approximately 50 percent of mean annual precipitation contributes to mean annual runoff, and about 70 percent of total annual flow occurs from June through August (Hanson n.d.) Flooding potential from rapid snow melt or a heavy storm is greatest during this period.

Stream gradients vary from 80 m/km or more in steep terrain to 0.13 m/km for the Bow River just above Banff townsite. Stream courses and gradients are strongly controlled by topography.

Lakes are also controlled by topography, though Lake Minnewanka, the largest lake in Banff, was created for hydroelectric power production. Other lakes are dammed by natural means (e.g. landslides, moraines, fans) or are in natural depressions such as kettles. Where accessible, they are important for recreation.

Subsurface flow is important, especially in areas of limestone, such as the spectacular example of karst between Medicine Lake and Maligne Canyon in Jasper (Brown 1973). Hot springs occur in both Banff and Jasper, and discovery of the Cave and Basin near Banff townsite in 1883 led to the creation of Canada's first National Park.

SURFACE EXPRESSION

Main physiographic features of Banff and Jasper may be traced to mountain building processes and subsequent erosion, with the Pleistocene glaciation a significant event. Vestiges of this glaciation and the processes involved are still active in the glaciers and icefields at high elevations that chiefly occur near the Continental Divide. Both glacial and postglacial surface features are described in the geomorphology section the Ecosite descriptions, and the legends.

PHYSIOGRAPHY AND PEOPLE

Physiography affects land use in the parks in many ways. Self-evident relationships include:

1. amenable topography and climate that make the Montane Ecoregion subject to the most intense land use in the parks
2. the passes providing transportation and utility corridors with attendant land use pressures
3. the combined influence of structure and glaciation that results in aesthetic lakes in cirques on the eastern sides of individual ranges, thus attracting development.

CLIMATE

OVERVIEW

Climatic data for Banff and Jasper National Parks are scarce. Janz and Storr (1977) provide the most comprehensive climatic overview for the contiguous National Parks within the Canadian Rocky Mountains.

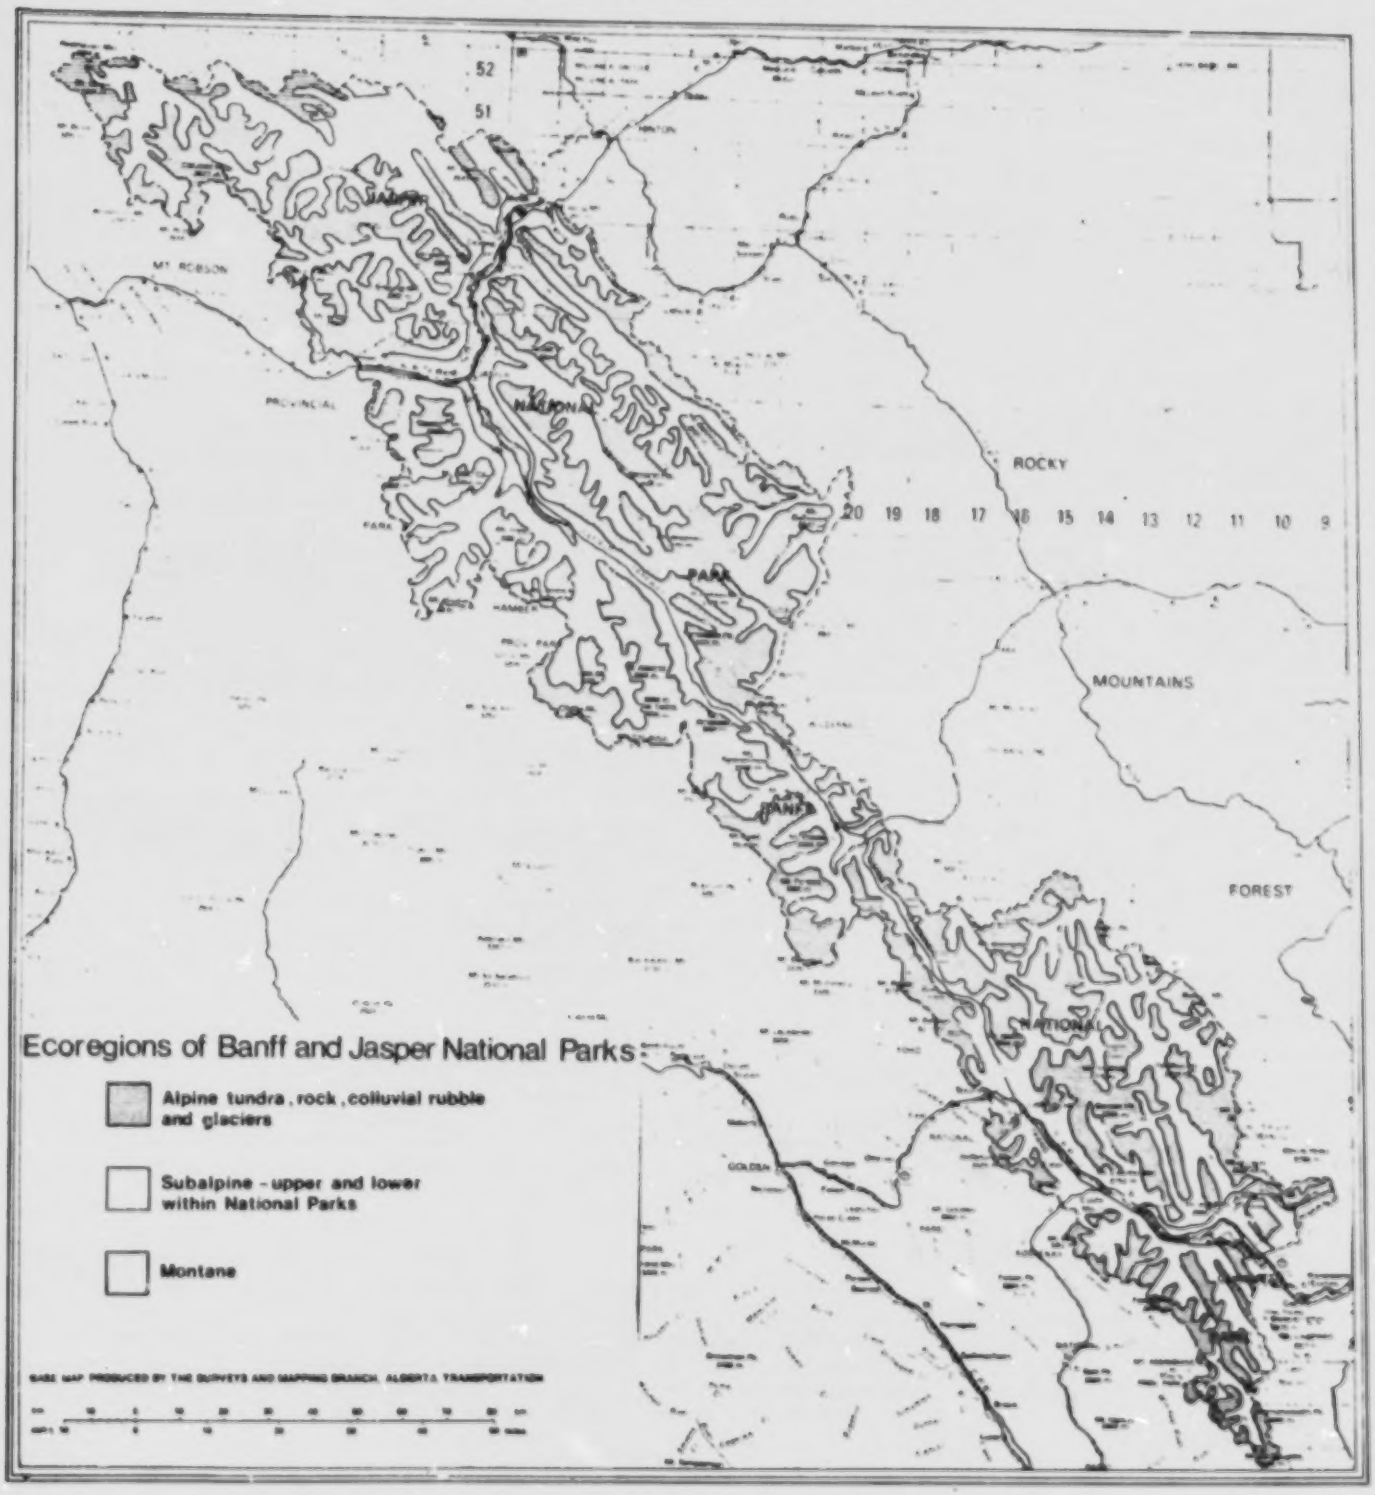
The macroclimate of Banff and Jasper is continental with long winters which can be cold and short summers that are cool with occasional hot spells. According to Koeppen's climatic classification (Trewartha 1957) most valley floors and lower slopes have a Dfc climate (Cold Snowy Forest Climate with no distinct dry season; cool short summers).

Both parks are subject to the same air masses and weather systems that migrate across western Canada at mid-latitudes. However, the mountain topography modifies macroclimate creating mesoclimatic and microclimatic gradients. The predominant northwest-southeast orientation of mountain ranges and valleys is nearly perpendicular to the prevailing winds aloft and influences precipitation distribution, winds, and the intrusion of Arctic air from the prairies to the east. Topography, especially aspect and elevation, causes climatic variation over short distances.

CLIMATE AND ECOREGIONS

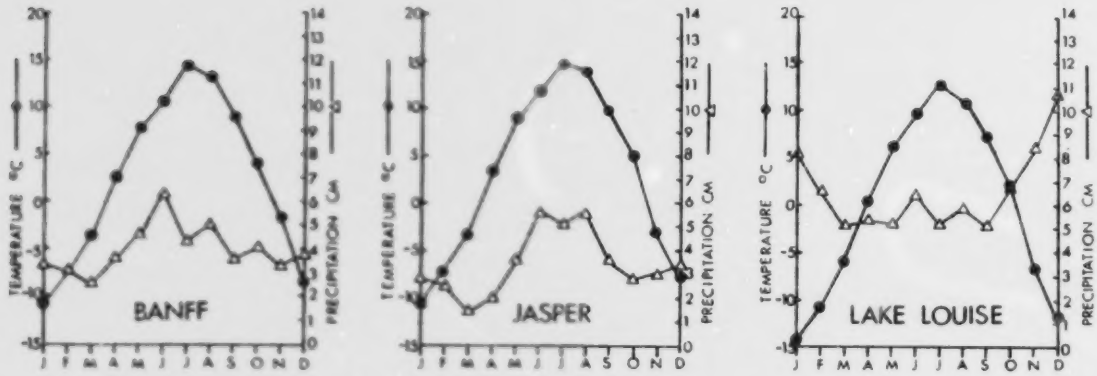
Lack of sufficient climatic data makes it impossible to classify Banff and Jasper, at scales of 1:250,000 and larger, using climatic data solely. However, vegetation, as a biotic component of an ecosystem, reflects climate. Thus, vegetation differences at a high level of generalization have been used to indicate climatic units. Based primarily on vegetation physiognomy and composition, four units have been delineated: Montane Ecoregion, Subalpine Ecoregion with Lower Subalpine and Upper Subalpine subunits, and Alpine Ecoregion. An approximation of their distribution is shown in Fig. 2.

Fig. 2. Ecoregions of Banff and Jasper National Parks



The most complete climatic data are available for the Montane Ecoregion. Fig. 3 illustrates temperature and precipitation data for Banff and Jasper townsites, both located in the Montane, and Village Lake Louise, located in the Lower Subalpine.

Fig. 3. Mean monthly temperature and precipitation for Banff and Jasper townsites and Village Lake Louise.



THE MONTANE ECOREGION

The climate of the Montane Ecoregion is the warmest and driest in the two parks. Mean yearly temperature is 2° to 3° C, based on Banff and Jasper townsite data. Average annual precipitation is about 465 mm (Tables 5 and 6) with summer precipitation being slightly greater than winter precipitation (Fig. 3).

Although the Montane is generally the warmest Ecoregion, it probably has the greatest temperature fluctuation. Extreme minimum temperatures in the range of −50° to −54° C (such low temperatures are rare) have been experienced in the main valleys below 1500 m (Janz and Storr 1977). These are related to temperature inversions with little mixing by wind and invasion of cold Arctic air from the north. Extreme maxima are of the order of 38° C in valleys below 1200 m but temperatures above 32° C are relatively rare (Janz and Storr 1977). Frequency of summer frost in the Montane is low and also indicates relatively mild climate.

Winds in the Montane are slightly stronger and more frequent than in other areas because valleys mapped as Montane are oriented approximately parallel to the prevailing westerlies aloft. Warm winter winds (chinooks) from Pacific air masses raise winter temperatures and the Montane Ecoregion is intermittently snowfree.

THE SUBALPINE ECOREGION

The Subalpine Ecoregion occurs at elevations above the Montane Ecoregion and is cooler and moister. The mean yearly temperature is about 0° C at low elevations, based on the Village Lake Louise data, and decreases with increasing elevation (i.e. about 0.5° C/100 m; summer lapse rate). Precipitation increases with elevation and the average annual precipitation of the Upper Subalpine (763 mm) is greater than the Lower Subalpine (665 mm), based on data from a few stations (Tables 5 and 6). Winter precipitation is greater than summer precipitation (Fig. 3) and the

2 Sacramento Storage Gauge (usually recorded twice a year)

incidence of measurable summer snowfall is greater than in the Montane. Precipitation in eastern portions of the parks appears to be lower than in western regions. This trend is supported by the scattered occurrence of Cryosolic soils (Achuff and Coen 1980) and dry grassland and shrubland vegetation in eastern subalpine areas. Conversely, Janz and Storr (1977) describe the area from Athabasca Pass to Freshfield Icefield (the Icefields area) as having an abnormally high precipitation regime relative to other areas of the parks.

Temperature fluctuation is narrower in the Subalpine than in the Montane. Janz and Storr (1977) indicate that the occurence of extreme minima in the −48° to −54° C range is rare above 1500 m elevation. Extreme maximum temperatures are lower than in the Montane because of a decrease with elevation that is probably similar to the lapse rate of mean maximum temperature (i.e. about 0.7° − 0.8° C/ 100 m, Janz and Storr 1977). Data from Bow Pass (6 years record, Janz and Storr 1977) and Mt. White (2.5 years record) in Banff indicate extreme maxima of 28° to 29° C in the Upper Subalpine at 1850 to 1970 m elevation.

Winds are generally light in the Subalpine, although there is evidence of wide variation, related mostly to topography. Thus, winds are important in east−west trending valleys and passes that traverse the mountain ranges, and also at higher elevations as indicated by stunted and krummholz open forest, and on exposed nonforested localities such as grasslands.

THE ALPINE ECOREGION

The Alpine Ecoregion occurs at elevations above the Subalpine Ecoregion and is the coldest in Banff and Jasper. Cool mean temperature projections are based on the trends of temperatures at lower elevations. Likewise, the temperature range is narrower in the Alpine (Janz and Storr 1977). This trend also extends to extreme maxima and minima. Precipitation increases with altitude from the Montane Ecoregion upward into the Alpine, but somewhere in the Alpine the trend may reverse. The lack of forest vegetation demonstrates the rigorous climate of the Alpine Ecoregion.

Winds are important in the Alpine. Janz and Storr (1977) report that all areas above about 2300 m are windy but winds may be light for several days in succession, particularly in summer. Erodible, exposed surfaces are often deflated and snow is redistributed by wind. Complex vegetation patterns in the Alpine are often linked to varying topographic exposures and resultant snow depth variability.

GEOLOGY

INTRODUCTION

Banff and Jasper lie in the southern portion of the Rocky Mountain Thrust Belt, the southeasterly−most sector of Canada's Cordilleran Orogen. This orogen represents the present state of evolution of the Cordilleran Geosyncline. Regional setting and stratigraphic and structural frameworks are outlined by Douglas et al. (1970) and Price and Mountjoy (1970a).

STRATIGRAPHIC FRAMEWORK AND ECOLOGICAL LAND CLASSIFICATION

Three categories of bedrock in Banff and Jasper are significant to this Ecological Land Classification. These are:

1. noncalcareous, medium and coarse grained clastic
2. noncalcareous, medium and fine grained clastic
3. carbonate and calcareous clastic.

This grouping was chosen because of the influence of these lithologies on unsorted genetic materials (Table 7) The stratigraphic column and named Groups and Formations in which these

lithologies occur are shown in Fig. 4.

Table 7. Correlation of generalized bedrock lithology with calcareousness and textural groups of unsorted genetic materials.

Generalized Bedrock Lithology	Calcareousness and Texture of Unsorted Genetic Material
Noncalcareous, medium and coarse grained, clastic	Noncalcareous, coarse textured
Noncalcareous, medium and fine grained, clastic	Noncalcareous, medium textured
Carbonate and or calcareous clastic	Calcareous, medium textured

STRUCTURAL FRAMEWORK AND ECOLOGICAL LAND CLASSIFICATION

Orogeny and subsequent erosion has produced four northwest–southeast trending geological subprovinces in the Rocky Mountains, only two of which are well expressed in Banff and Jasper. Regional stratigraphy, structure, and topography distinguish these subprovinces, and distribution is shown in Fig. 5. Typical Foothills subprovince essentially does not occur in the parks. The Front Ranges subprovince is regionally represented by southwest dipping Devonian to Jurassic rocks arranged in subparallel ridges of resistant Paleozoic carbonate separated by valleys carved from recessive Mesozoic clastics. Regionally, Main Range beds are gently dipping and the mountain ranges are not linear. Typically, peaks are capped by pre–Devonian carbonates and grade downwards in time with decreasing elevation to clastics of the early miogeosyncline (Fig. 4).

Some Ecosites have a direct link to a specific geological setting. For instance, the source strata for an Ecosite mapped on noncalcareous, medium textured till located in the Main Ranges were probably of the Miette Group (Figs. 4, 5, Table 7). Distribution of certain Ecosites correlates closely with distribution of Groups and Formations as shown on maps prepared by the Geological Survey of Canada. Geological maps complementing this Ecological Land Classification are by Price and Mountjoy (1970a,b), (197la,b,), (1972a,b), Cook (1975), Price et al. (1978), Price et al. (1979), and Mountjoy (1980).

GEOMORPHOLOGY

INTRODUCTION

Soil and vegetation development is influenced by landform. Landform classes are defined in terms of genetic material, surface expression, and modifying processes (C.S.S.C. 1978b). Genetic materials are emphasized in this section and are classified, with some modifications to taxa definitions, according to the C.S.S.C. (1978b) landform classification system.

Genetic materials are organized into four groups: consolidated (bedrock), unconsolidated mineral, organic, and ice. The unconsolidated mineral group is subdivided according to mode of formation or deposition. Ten genetic material classes (modified from C.S.S.C 1978b) are recognized. These are listed in Table 4 in order of increasing source diversity, increasing influence of depositional agents, and decreasing influence of bedrock lithology.

Fig. 4. Generalized time scale and stratigraphic column for Banff and Jasper.

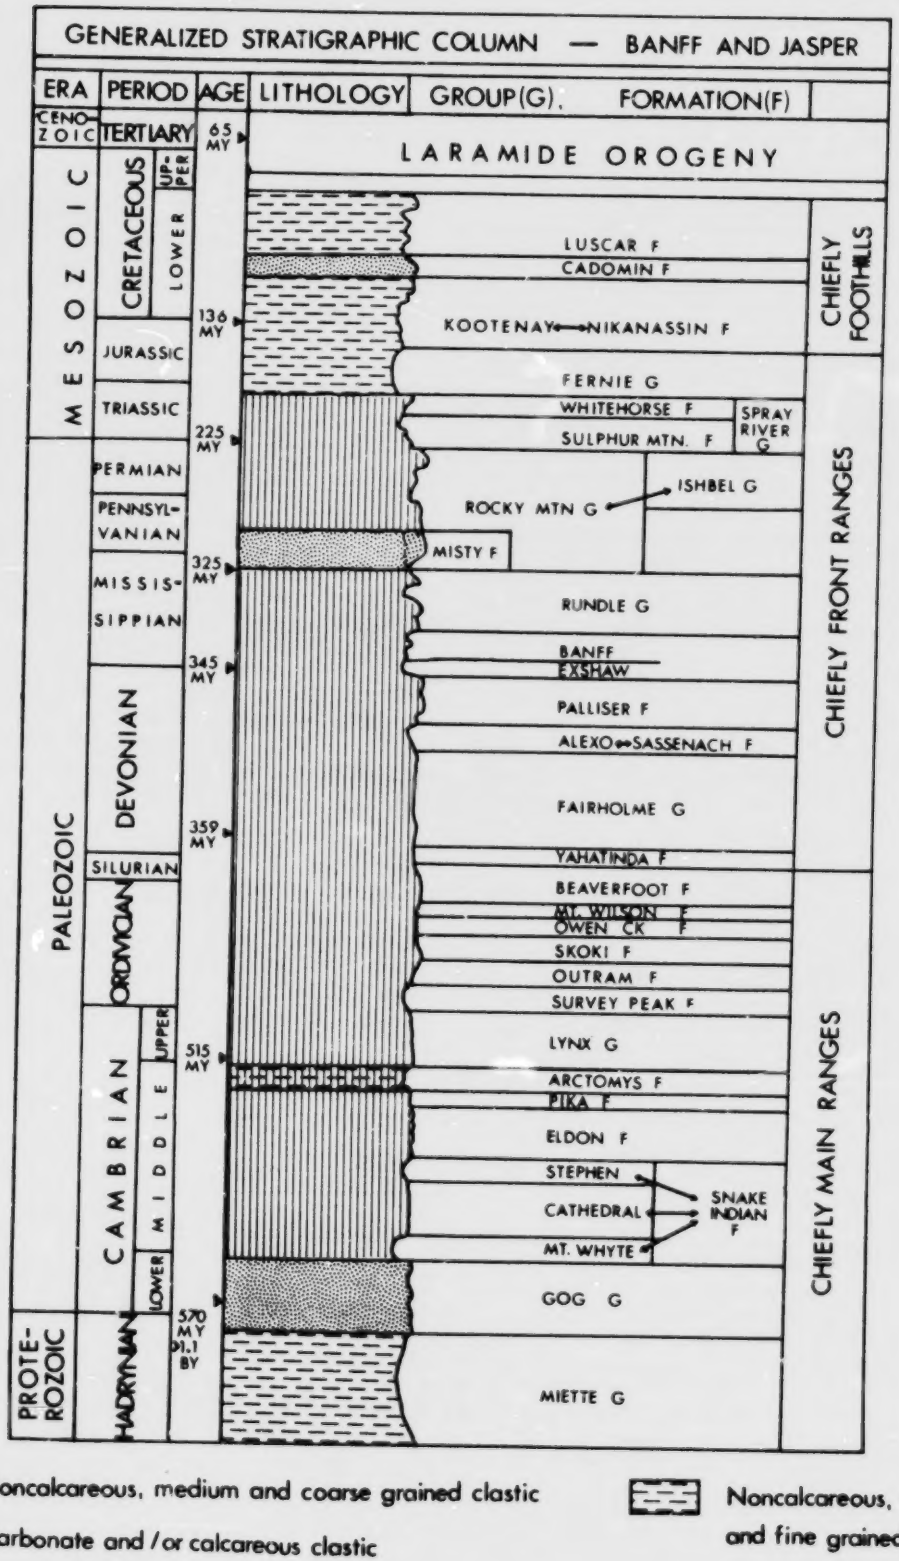

Fig. 5. Geologic subprovinces of Banff and Jasper.

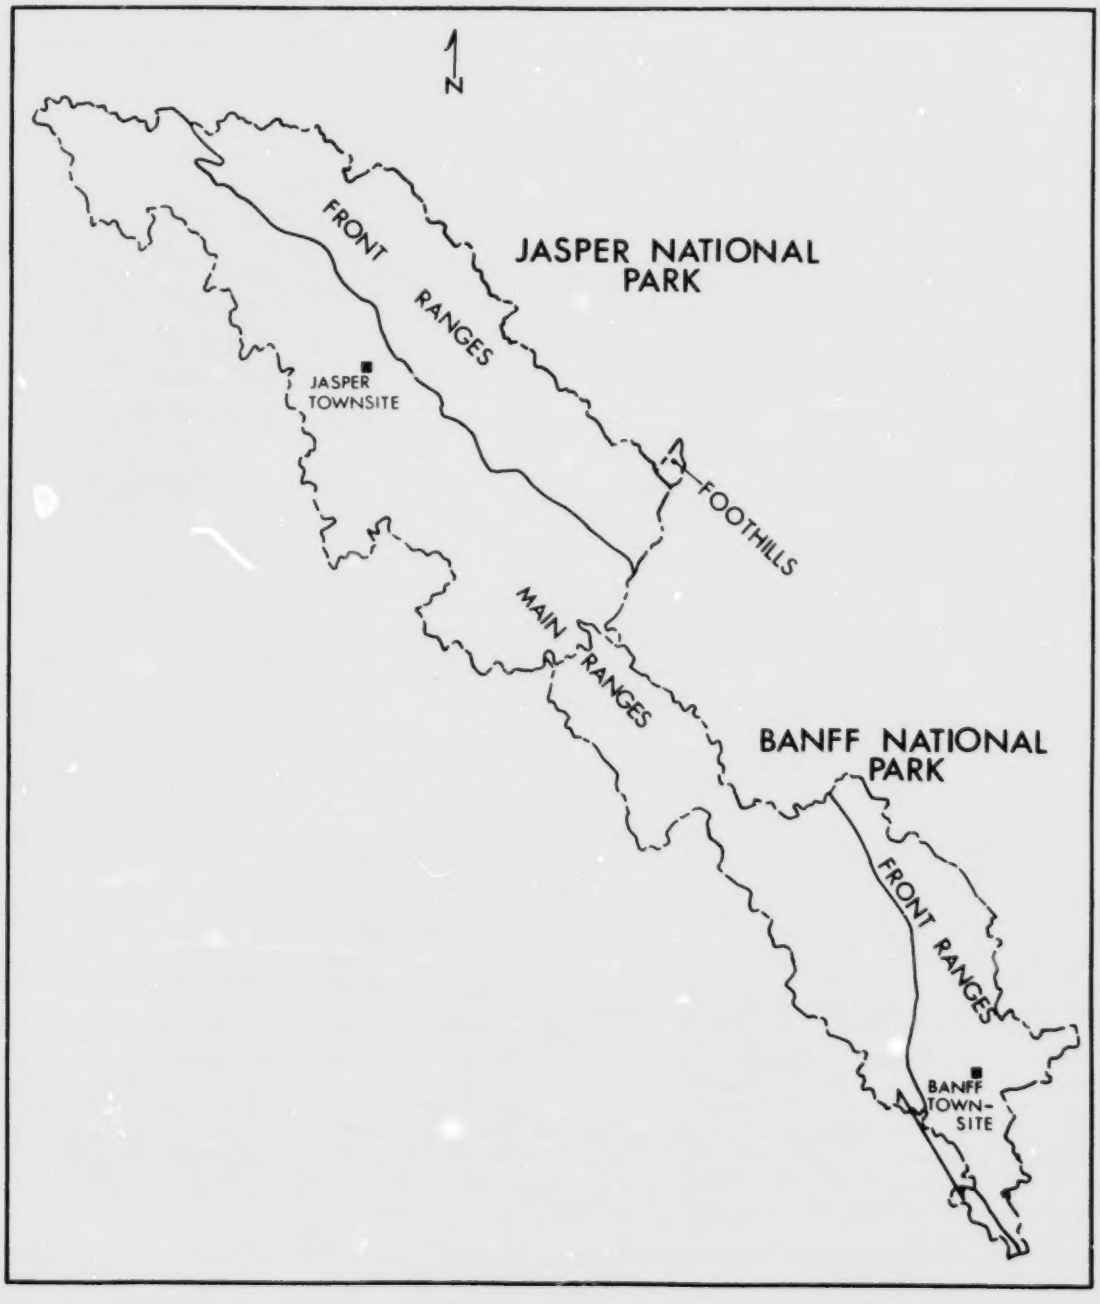

Genetic material classes are further subdivided according to textural and chemical (calcareousness) properties imparted either by source area lithology or modified by depositional media. Twenty genetic material units, listed in Table 8, are defined specifically for the Banff–Jasper Ecological Land Classification.

Table 8. Characteristics of modal unconsolidated mineral genetic materials.

	Medium	Genetic Material Symbol*	Genetic Material Class†	Characteristics: Calcareousness	Characteristics: Texture	Genetic Material Unit
Genetic material derived from increasingly diverse bedrock lithology	Rock (*in situ* and failed)	R^{U*}	Residual	noncalcareous	medium	Residuum A
				calcareous	medium	Residuum B
		C^{A*}	Landslide	variable	variable	Landslide material
	Gravity	C	Colluvial	noncalcareous	coarse	Colluvium A
				noncalcareous	medium	Colluvium B
				calcareous	medium	Colluvium C
	Ice	M	Morainal	noncalcareous	coarse	Till A
				noncalcareous	medium	Till B
				calcareous	medium	Till C
		MI^{G*}	Ice Contact Stratified	noncalcareous	coarse	Ice Contact Stratified Drift A
				calcareous	variable	Ice Contact Stratified Drift B
	Flowing Water	I^{G}	Glaciofluvial	noncalcareous	coarse	Glaciofluvial material A
				calcareous	coarse	Glaciofluvial material B
		I	Fluvial	noncalcareous	coarse-stratified	Fluvial material A
				calcareous	coarse-stratified	Fluvial material B
	Still Water	I^{L*}	Fluviolacustrine	altered	fine-stratified	Fluviolacustrine material A
				calcareous	fine-stratified	Fluviolacustrine material B

	Air	I	Eolian	calcareous	medium	Eolian material A
				altered	medium	Eolian material B

Restricted bedrock source — Unsorted — Increasingly diverse sources — Increasingly sorted

* The abbreviations used to designate Genetic Materials are according to C.S.S.C. 1978b except for R^{U}, C^{A}, MI^{G}, and I^{G} which are defined in this section.

† Modified from C.S.S.C. (1978b).

RESIDUAL GENETIC MATERIAL

Residual material in Banff and Jasper is physically and chemically weathered bedrock and is designated by landform symbol R^{U}. It includes failed bedrock that retains some original bedding structure and is nonfragmental. Residual material is derived from recessive, medium and fine grained, clastic bedrock. It may be either noncalcareous or calcareous and is divided into two genetic material units (Residuum A and Residuum B) on that basis.

Residuum A is normally medium textured and noncalcareous (acidic), with dominant characteristics as presented in Table 9. It is the dominant residual material of the Main Ranges. Residuum B is normally medium textured and calcareous, hence neutral to moderately alkaline in reaction (Table 9). It is distributed primarily in the Front Ranges. Fine earth content decreases and coarse fragment content increases with depth in sola developed in both residual materials. Residuum A is defined as having sola with pH $\leq$ 5.5 to a depth of 25 cm below the top of the B horizon. Residuum B is associated with sola having pH > 5.5.

Surface expression of both residual materials is inclined, hummocky, or ridged depending on the nature of the underlying bedrock and whether or not slope failure has occurred. Slopes commonly range to 45%. Solifluction and cryoturbation are common modifying processes in the

Table 9. Characteristics of residual genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Residuum A	Noncalcareous, medium to fine grained, clastic bedrock (e.g. Miette Group)	20-60% sand and 5-20% clay	50-90%	Noncalc.	4.5-6.0
Residuum B	Calcareous, medium to fine grained, clastic bedrock (e.g. Spray River Group)	20-60% sand and 5-20% clay	50-90%	<35% $CaCO_3$ equiv.	7.0-8.0

Alpine Ecoregion.

LANDSLIDE GENETIC MATERIAL

Landslide genetic material in Banff and Jasper is generated by rapid, gravity-induced movement of mineral material downslope en masse. It is designated by the landform symbol c^ and represents a subset of colluvial material as defined by C.S.S.C. (1978b). Landslides are sporadically distributed throughout the parks and consist of failed bedrock of various lithologies. Occasionally they originated from unconsolidated mineral material.

Coarse fragments comprise 50 to 100% of the material by volume and are rubbly (angular fragments <256 mm) and blocky (angular fragments >256 mm). Most landslides are fragmental at depth. Surfaces are often exceedingly to excessively stony. Fine earth textures vary from medium to coarse, spanning the silt loam, loam, sandy loam, and loamy sand textural classes defined by C.S.S.C. (1978a). Much of the fine earth fraction in soils on older slides is Eolian Material B. Soil and vegetation develop more rapidly on finer grained slides, while coarsest portions have sparse soil and vegetation regardless of age. Calcareousness ranges from non to extremely calcareous. Both extremes may occur within one slide derived from contrasting materials.

Surface expression of landslide material is hummocky, often superimposed on a rising, inclined slope. Hummocks are produced by the landslide process, while the overall incline reflects bedrock control at some depth. Other genetic materials, especially morainal material on valley walls and floors, many underlie landslides at variable depth.

COLLUVIAL GENETIC MATERIAL

Colluvial genetic material in Banff and Jasper is generated by the slow or rapid, gravity induced, downslope displacement of isolated mineral fragments. It is designated by the landform symbol c and represents a subset of colluvial material as defined by C.S.S.C (1978b). Soil creep and snow avalanching, with avalanche related fluvial activity including mudflows, are the processes responsible for colluvial material accumulation. This material is generally postglacial and mantles steep valley walls. Three colluvial genetic material units (Colluvium A,B, and C) are distinguished based on textural and chemical properties (Table 10).

Table 10. Characteristics of colluvial genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Colluvium A	Noncalcareous, medium to coarse grained, clastic bedrock (e.g. Gog Group quartzites)	60-85% sand and 0-10% clay	50-90%	Noncalc.	4.3-6.0
Colluvium B	Noncalcareous, medium to fine grained, clastic bedrock (e.g. Miette and Fernie Groups)	20-60% sand and 5-20% clay	35-90%	Noncalc.	4.3-6.0
Colluvium C	Medium to fine grained, carbonate and calcareous clastic bedrock	20-60% sand and 0-25% clay	35-90%	30-95% $CaCO_3$ equivalent	7.0-7.8

Colluvium A is normally coarse textured and noncalcareous (acidic). It is most extensive in the Main Ranges. Colluvium B is normally medium textured and noncalcareous (acidic). Colluvium C is usually medium textured and calcareous, hence neutral to mildly alkaline in reaction.

Low lime colluvial materials are differentiated into Colluvium A and B versus C based on pH of the sola developed on them. Colluvium A and B produce sola with pH $\leq$5.5 at a depth of 25 cm below the top of the B horizon. Colluvium C produces sola with pH >5.5. Colluvium that is texturally transitional between Colluvium A and B is distinguished by coarse fragments and soil development. Colluvium A generally has more coarse fragments, than B or C. Colluvium B is characterized by coarse fragments which are dominantly shales and slates. Soils developed on Colluvium A generally have deeply developed sola and thick, well developed eluvial (Ae) horizons. Colluvium B soils have thin sola and thin to absent Ae horizons. Further, the lithology of source bedrock aids in differentiating the colluvial material units.

Surface form is usually linear and expressed as blankets, veneers, and aprons. It is controlled by the amount of deposition and by the underlying bedrock. Slopes commonly range from 45 to 100%; their continuity may be broken by one or more bedrock outcrops. Soil creep and snow avalanching are the most common modifying processes. Slope failure, sheet erosion, solifluction, and cryoturbation occur locally.

MORAINAL GENETIC MATERIAL

Morainal material (till) is unsorted and unstratified drift deposited by and underneath a glacier without subsequent reworking by glacial meltwater. Morainal deposits occur extensively and are designated by the landform symbol $_M$. Morainal topography frequently dominates valley walls, valley floor benchlands, cirque basins, cols, and shoulders. Till is occasionally intimately associated with ice contact stratified genetic material along valley floors. Both are collectively considered glacial deposits. Three morainal genetic material units (Tills A,B, and C) are differentiated by textural and chemical properties (Table 11).

Table 11. Characteristics of morainal genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Till A	Noncalcareous, medium to coarse grained, clastic bedrock (e.g. Gog Group quartzites)	60-85% sand and 0-10% clay	35-70%	Noncalc.	4.3-6.0
Till B	Noncalcareous, medium to fine grained, clastic bedrock (e.g. Miette and Fernie Groups)	30-60% sand and 5-25% clay	20-50%	Noncalc.	4.3-6.0
Till C	Medium to fine grained, carbonate and calcareous clastic bedrock	20-60% sand and 5-27% clay	20-50%	15-85% $CaCO_3$ equivalent	7.0-7.8

Till A is normally coarse textured and noncalcareous (acidic). It is most extensive in the Main Ranges. Till B is normally medium textured and noncalcareous (acidic). Till C is usually medium textured and calcareous (neutral to mildly alkaline).

Low lime Tills A and B are differentiated from Till C by having soils with pH $\leq$ 5.5 at a depth of 25 cm below the top of the B horizon. Till C is characterized by sola with pH >5.5. Till that is near the medium-coarse textural class boundary is recognized as Till A when it is dominated by a high coarse fragment content (most of which are subrounded quartzites). Soils developed on Till A generally have deeply developed sola and thick, well developed eluvial (Ae) horizons. Till B has coarse fragments which are dominantly shales and slates. The lithology of source bedrock further aids in distinguishing the three tills.

Surface form is usually linear on valley walls and forms blankets overlying inclined bedrock. Ridged and hummocky surfaces characterize benchlands, cirques, cols, and shoulders. These most often reflect underlying bedrock but in some areas reflect deposition or postglacial slope failure. Linear slopes reflecting stream erosion are common along some valley floors. Slopes commonly range from 5 to 70%. Slope failure, gullying, and snow avalanching are common surface modification processes that affect morainal landforms. Sheet erosion, soil creep, solifluction, and cryoturbation occur locally, the latter two at high elevations on the medium textured tills.

ICE CONTACT STRATIFIED GENETIC MATERIAL

Ice contact stratified drift is partially sorted material deposited by glacial ice but with concomitant and subsequent reworking, locally, by flowing and ponded glacial meltwater. The result is extreme vertical and lateral textural variability over short distances, except where coarse to medium grained source strata preclude the incorporation of abundant clay and silt sized particles. In essence, ice contact stratified drift, designated by the landform symbol M^{fg}, encompasses an intimate, random mixture of morainal, glaciofluvial, and, occasionally, glaciolacustrine sediments individually inseparable at a scale of 1:50,000. Ice contact stratified drift and

morainal material (till) are collectively considered glacial deposits. Two ice contact stratified genetic material units (Ice Contact Stratified Drift A and Ice Contact Stratified Drift B) are differentiated primarily on chemical properties and secondarily on textural properties (Table 12).

Table 12. Characteristics of ice contact stratified drift genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Ice contact stratified Drift A	Noncalcareous, medium to coarse grained, clastic bedrock (e.g. Cog Group quartzites)	60-100% sand and 0-10% clay	5-70%	Noncalc.	4.3-6.0
Ice contact stratified Drift B	Medium to fine grained, carbonate and calcareous clastic bedrock	0-100% sand and 0-60% clay	5-70%	15-85% $CaCO_3$ equivalent	7.0-7.8

Ice Contact Stratified Drift A is normally noncalcareous (acidic) and coarse textured. It occurs primarily in the Main Ranges. A noncalcareous textured variant, derived primarily from Miette Group slates and shales, occurs in a few areas of the Main Ranges. Ice Contact Stratified Drift B is normally variably textured and calcareous (neutral to mildly alkaline).

Low lime, ice contact stratified materials are differentiated into Ice Contact Stratified Drift A or B based on pH of the sola developed on them. Ice Contact Stratified Drift A produces sola with pH $\leq$5.5 to a depth of 25 cm below the top of the B horizon. Soils associated with this genetic material unit tend to be deeply developed and have thick, well developed eluvial (Ae) horizons. Ice Contact Stratified Drift B produces soils with thin sola that have pH >5.5 to a depth of 25 cm below the top of the B horizon.

Ice contact stratified drift forms moraine-like landforms near valley floors, on valley floor benchlands, and, occasionally, on lower valley wall slopes. Hummocky, ridged, and inclined surface expressions are typical. These may be of strictly depositional origin, reflect the underlying bedrock, or be the result of stream erosion. Channelling (Eroded modifier, C.S.S.C. 1978b) and gullying are the most important modifying processes, the former often influencing landform surface expression. Other modifying processes of a more local distribution include slope failure, snow avalanching, sheet erosion and soil creep.

GLACIOFLUVIAL GENETIC MATERIAL

Glaciofluvial genetic material is deposited by bodies of flowing water in which the flow volume and sediment load are principaliy controlled by melting glacial ice. It is designated by the landform symbol F^G and is regarded as a proglacial deposit. Two glaciofluvial genetic material units (Glaciofluvial material A and B) are differentiated by chemical properties (Table 13).

Glaciofluvial material A is normally coarse textured and noncalcareous (acidic). Glaciofluvial material B is normally coarse textured and calcareous (neutral to moderately alkaline).

Table 13. Characteristics of glaciofluvial genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Glaciofluvial material A	Noncalcareous glacial deposits	60-100% sand and 0-5% clay	35-70%	Noncalc.	4.3-6.0
Glaciofluvial material B	Calcareous glacial deposits	60-100% sand and 0-5% clay	35-70%	>10% $CaCO_3$ equivalent	7.0-8.0

Low lime glaciofluvial materials are differentiated into Glaciofluvial material A or B based on pH of the sola developed on them. Glaciofluvial material A produces sola with pH $\leq$5.5 to a depth of 25 cm below the top of the B horizon. Soils associated with this genetic material unit tend to be deeply developed and have thick, well developed eluvial (Ae) horizons. Glaciofluvial material B produces sola with pH >5.5 to a depth of 25 cm below the top of the B horizon.

Glaciofluvial deposits are distributed on valley floors and lower benchlands primarily in broad valleys at low elevations. Terrace is the most common surface form of stable landforms. Slopes are often complex with the majority of any surface made up of linear terrace treads with <5% slope. Short risers between terrace levels usually have slopes ranging from 30 to 70%. Actively aggrading glaciofluvial deposits have level and fan surface expressions with slopes <5%. Abandoned channels (Eroded modifier, C.S.S.C. 1978b) are often present.

FLUVIAL GENETIC MATERIAL

Fluvial (alluvial) material encompasses sediment deposited by stream channel sedimentation and mudflow processes (Thornbury 1954, Winder 1965, Russell 1972) and is designated by the landform symbol F. Two fluvial genetic material units (Fluvial material A and B) are differentiated based on chemical properties (Table 14).

Fluvial material A normally displays stratified coarse textures and is noncalcareous (acidic). Fluvial material B normally displays stratified coarse textures and is calcareous (neutral to moderately alkaline).

Low lime fluvial materials are differentiated into Fluvial material A or B based on pH of the sola developed on them. Fluvial material A produces sola with pH $\leq$5.5 to a depth of 25 cm below the top of the B horizon. Fluvial material B produces sola with pH >5.5.

Fluvial landscapes are most abundant along valley floors including benchlands. Two surface form groups, both with linear slopes, are characteristic. Level plains (floodplains), with slopes ranging from 0 to 2%, contain the major streams that formed them. Fans and aprons, with slopes ranging from 2 to 45%, occur along the toes of steeper slopes from which their sediments originated. Fluvial veneers and blankets occur in some cirque basin, col, shoulder, and valley floor localities. Active and abandoned channels (Eroded modifier, C.S.S.C. 1978b) are common on fluvial landform surfaces. Snow avalanching and solifluction are other modifying processes, but these occur locally, particularly at high elevations.

Table 14. Characteristics of fluvial genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Fluvial material A	Noncalcareous bedrock, residual, landslide, colluvial, and glacial materials	15-90% sand and 0-25% clay, often stratified	0-70%, often stratified	Noncalc.	4.3-6.0
Fluvial material B	Calcareous bedrock, residual, landslide, colluvial, and glacial materials	15-90% sand and 0-25% clay, often stratified	0-70%, often stratified	5-85% $CaCO_3$ equivalent	7.0-8.0

FLUVIOLACUSTRINE GENETIC MATERIAL

Fluviolacustrine material encompasses relatively fine grained sediments deposited by slowly moving water, both glacial and nonglacial. The depositional environment is considered to be low energy fluvial but, by its textural characteristics, fluviolacustrine material does not fit the fluvial definition of C.S.S.C. (1978b). It is designated by the landform symbol [illegible]. Two fluviolacustrine genetic material units (Fluviolacustrine material A and B) are differentiated by chemical properties and geomorphic environments (Table 15).

Table 15. Characteristics of fluviolacustrine genetic material units.

Genetic Material Unit	Derivation	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Fluviolacustrine material A	Sheet erosion on other genetic materials, local deposition on other surfaces.	0-20% sand and 15-50% clay, often stratified	0-5%	pedogenic alteration	pedogenic alteration
Fluviolacustrine material B	Fluvial erosion of various deposits, low energy deposition on backwater portions of floodplains	0-20% sand and 10-40% clay, often stratified	0-5%	5-70% $CaCO_3$ equivalent	6.8-7.8

Fluviolacustrine material A encompasses fine textured and stratified, chemically altered, slope wash sediment deposited by nonglacial, unconfined water flow. It usually occurs as thin (usually <30 cm), mineral surface veneers overlying morainal, glaciolacustrine, and fluvial landforms with slopes of 0 to 30%. This material usually comprises the upper sola of soils where pedogenic weathering is strongest, hence the altered chemical properties. Fluviolacustrine material A comprised dominantly of reworked, Eolian material B has inherited the latter's primary mineral constituents and therefore, weathering frequently releases high amounts of free iron and aluminum oxide in the upper 30 cm.

Fluviolacustrine material B encompasses calcareous, fine, stratified sediment deposited by ponding of mainly glacial waters on backwater portions of floodplains, similar to those described by Smith (1972), and on delta-like floodplains at the heads of lakes, like those described by Smith (1975). It is the thickest and most stratified of the two fluviolacustrine material units and is confined to broad, valley floor floodplains where it overlies, interbeds with, and locally supplants fluvial and glaciofluvial sedements. Surface expression is level with slopes ranging from 0 to 1%. Slope continuity is frequently broken by numerous, shallow, abandoned and active stream channels meandering across the landscape (Eroded modifier, C.S.S.C. 1978b).

Fluviolacustrine genetic material is texturally similar to glaciolacustrine genetic material but exhibits greater textural variablility, a wider range of bulk density, and incorporation of thin, fibrous organic layers and pockets compared to the latter. Further, fluviolacustrine material is massive whereas glaciolacustrine material often exhibits varving and nonpedogenic subangular blocky structure. Glaciolacustrine material occurs in former lake basins and mantles, as blankets and veneers, gently sloping glacial landforms on benchlands. Fluviolacustrine sediments are associated with glacial, proglacial, and fluvial landforms as described above but these often do not occur in lake basins.

GLACIOLACUSTRINE GENETIC MATERIAL

Glaciolacustrine genetic material encompasses fine-grained sediment deposited in proglacial lake environments. It is designated by the landform symbol $^{L^G}$ and occurs primarily in the lower drainages of some tributary valleys of the Athabasca, North Saskatchewan and Bow River valleys. Glaciolacustrine material is texturally similar to fluviolacustrine genetic material but can be differentiated by stratification, bulk density, structural, and geomorphic environment parameters as outlined in the fluviolacustrine genetic material section.

Glaciolacustrine material is fine textured (0 - 10% sand and 30 - 50% clay) and calcareous (very strongly to extremely calcareous), hence neutral to mildly alkaline in reaction (pH 7.2 - 7.4). Noncalcareous glaciolacustrine material occurs rarely. Coarse fragments are usually absent but may range to 5% by volume.

Glaciolacustrine material commonly occurs as blankets and veneers overlying ridged, hummocky, and undulating glacial landforms of valley floor benchlands. Slopes commonly range from 0 to 10%.

EOLIAN GENETIC MATERIAL

Eolian sediment is deposited by wind. In Banff and Jasper, eolian deposits, also termed loess, are well sorted and dominated by silt (rarely <50%). Designated by the landform symbol ^{E}, Eolian Genetic Material is probably the most extensive unconsolidated mineral genetic material, but only in limited areas does it consistently exceed 30 cm in thickness. Two eolian genetic material units (Eolian material A and B) are differentiated based primarily on chemical properties (Table 16).

Eolian material A encompasses calcareous, medium textured sediment. Occurrences are restricted to valley floors, benchlands, and lower valley wall slopes in the Athabasca and Howse/North Saskatchewan River valleys at low elevations of the Montane Ecoregion. It exists

Table 16. Characteristics of eolian genetic material units.

Genetic Material Unit	Dominant Source	Usual Textural Properties		Usual Chemical Properties	
		Fine Earth	Coarse Fragments	Calcareousness	pH
Eolian material A	Braided river channels with extensive bare mineral soil	0-40% sand and 5-20% clay	0-5%	15-70% $CaCO_3$ equivalent	7.3-8.3
Eolian material B	Local unconsolidated and consolidated materials plus volcanic ash	10-50% sand and 0-25% clay	0-5%	pedogenic alteration	pedogenic alteration

as veneers and blankets overlying glacial deposits above the valley floor positions and as ridged landforms (dunes) on the Athabasca River valley floor. Slopes range from 5 to 70%. Processes modifying Eolian material A are primarily those which erode, mix, and rework surface layers. These include deflation, windthrow of trees, sheet erosion, stream channel overflow, and gullying. Eolian material A is presently aggrading with the rate of deposition decreasing upslope from the valley floors.

Eolian material B encompasses medium textured, chemically altered sediment. It occurs as thin (usually <30 cm), mineral surface veneers overlying a variety of landforms on all physiographic positions in all Ecoregions. It is most common on older, relatively stable surfaces such as morainal landscape. The deepest (15 to 30 cm) and most extensive deposits occur on stable surfaces in western Banff and southwestern Jasper. This material often comprises the upper sola of soils where pedogenic weathering is strongest, hence the altered chemical properties. Weathering of easily weatherable primary minerals is implicated in the characteristic strong pedogenic development in Eolian Material B. (Pettapiece and Pawluk 1972, Pawluk and Brewer 1975, King and Brewster 1976, and Smith 1979). Physical processes modifying Eolian material B are primarily those which erode, mix, and rework surface layers. These include sheet erosion, gully erosion, colluviation, avalanching, windthrow of trees, solifluction, and cryoturbation.

ORGANIC, CONSOLIDATED, AND ICE COMPONENTS

The organic component consists of peat deposits containing >30% organic matter by weight (>17% organic carbon) that may be as thin as 10 cm if they overlie bedrock but are otherwise >40 cm thick (C.S.S.C. 1978b). In Banff and Jasper the organic component is of limited areal extent and thinly mantles (rarely >1.2 m) glacial, proglacial, fluviolacustrine, and fluvial landforms in localities with ground water discharge and high water tables (very poor to poor drainage). It consists predominantly of moderately decomposed (mesic) fen peat designated by the landform symbol N, derived primarily from sedges and brown mosses. In several localities, the fen vegetation has been succeeded by open and closed forest. Fibric and humic layers and partially decomposed wood fragments may also occur in the section. The peat is medium acid to neutral (pH 5.5-7.5). Fen surface expression is horizontal or sloping and reflects the underlying mineral deposits. Slopes range from 0 to 10%.

The consolidated component (bedrock) consists of tightly packed lithified materials, excluding materials indurated by pedogenic processes, and is harder than 3 on Mohs' hardness scale. Bedrock underlies all other materials in the parks and outcrops in all areas, most often at high

elevations. Massive, resistant bedrock is more prominent in the landscape than recessive bedrock. It is the source of almost all unconsolidated mineral material in the parks.

The ice component encompasses ice and firn that forms by the compaction and recrystallization of snow. In Banff and Jasper, this includes glaciers, icefields, glacierettes, and firn. It occurs mainly in the Upper Subalpine and Alpine Ecoregions and is most extensive at higher elevations of the Main Ranges near the Continental Divide (Falconer et al. 1966). In some localities, ice is mantled by colluvial and landslide debris from adjacent steep slopes.

SOILS

FACTORS OF SOIL FORMATION

Five environmental factors are generally considered to affect soil formation. These are climate, living organisms, kind of parent material, relief, and time (or length of stability). The interaction of these soil-forming factors has resulted in many different kinds of soil throughout Banff and Jasper. The relative importance of each factor differs from place to place.

SOIL ORDERS IN BANFF AND JASPER

The soil taxonomy used in Banff and Jasper follows the Canadian System of Soil Classification (C.S.S.C. 1978b) Representatives of eight soil orders occur in the parks, including the Brunisolic, Luvisolic, Podzolic, Chernozemic, Cryosolic, Regosolic, Gleysolic, and Organic Orders.

BRUNISOLIC ORDER

The Brunisolic Order is broad in concept and, in Banff and Jasper, the most extensive relative to other orders, encompassing a wide range of characteristics. Four great groups occur in Banff and Jasper; their differentiation is based on solum reaction and A horizon characteristics.

Eutric and Melanic Brunisols have pH >5.5 at a depth of 25 cm below the top of the B horizon. These are associated with calcareous geomorphic materials. Dystric and Sombric Brunisols have pH $\leq$ 5.5 at a depth of 25 cm below the top of the B horizon. These are associated with non-calcareous geomorphic materials, including some with low lime content, and are less extensive than the Eutric and Melanic Brunisols.

Melanic and Sombric Brunisols are distinguished from Eutric and Dystric Brunisols by the presence of thick (10 cm or more) organo-mineral Ah horizons. Such horizons develop under non-forest vegetation where organic matter incorporation and humification are important processes.

B Horizon Characteristics of Brunisolic Soils

Brunisolic B horizons display a wide range of characteristics.

1. Brunisolic soils with weakly expressed and poorly differentiated B horizons are often associated with Regosolic soils on some geomorphically active terrain, such as steep colluvial landforms.
2. Eutric Brunisols occuring on warm, dry glacial and glaciolacustrine landforms, usually under lodgepole pine forests in the Montane and Lower Subalpine, frequently have B horizons with luvisol-like morphologies. Luvisolic soils are intimately associated. The Bm and Btj horizons of these Brunisolics display high clay contents compared to adjacent horizons, but structure and clay film development are weak and carbonate removal is incomplete.
3. Brunisolic soils with moderate or intermediate horizon development occur under intermediate mesoclimatic conditions or on stable genetic materials that do not

promote luvisolic or podzolic tendencies as a result of pedogenic weathering. Bm horizons of these Brunisolics are brownish colored and have low to moderate amounts of humus and free iron and aluminum oxides. Included are Eluviated Dystric Brunisols with duric tendencies (weak cementing) in lower B and BC horizons that are frequently developed on noncalcareous, coarse textured genetic material units, i.e. Till A, Ice Contact Stratified Drift A, and Glaciofluvial material A.

4. Brunisolic soils with strongly developed B horizons (podzolic tendencies) are associated with Podzolic soils under cool, moist Subalpine and Alpine conditions on stable landforms that include veneers of Eolian material B or Fluviolacustrine material A derived from Eolian material B (Table 8). The reddish, dark and strong brown Bm, Bfj, Bf or Bhf horizons of these Brunisolics are developed immediately above the parent material disconformity and have moderate to high, free iron and aluminum contents, weathered from the surface veneers. These B horizons also display increasing illuvial-humus content with elevation or with increasing wetness (imperfectly to poorly drained). This Brunisolic-Podzolic complex of soils is most extensive in western Banff and southwestern Jasper.

5. A variety of Brunisolic soils occurs under imperfectly to poorly drained conditions on sites affected by seepage. These are usually associated with Gleysolic and gleyed Podzolic soils. Gleyed Brunisols generally display weak mottling in a matrix background of moderate chroma within the upper 50 cm of mineral soil. A variety of climatic, geomorphic, and hydrologic factors contribute to the varying intensity of gleization across seepage affected landscape.

A Horizon Characteristics of Brunisolic Soils

The A horizons of Brunisolic soils exhibit a wide range of characteristics. They may be absent where current or recent disturbances have destroyed them or inhibited their development. On more stable slopes, eluvial (Ae) horizons are common under forest vegetation and, where >2 cm thick, are diagnostic for Eluviated subgroups within the Brunisolic Order. Organomineral Ah horizons associated with Brunisolic and other soils occur under tundra vegetation in the Alpine and Alpine-Upper Subalpine ecotone and under grassland and dry shrubland vegetation in the Subalpine. In both environments, the Ah horizon thickness is variable and largely controlled by the kind and degree of surface disturbance. The variable Ah horizon thickness results in the intimate association of Eutric with Melanic Brunisols and Dystric with Sombric Brunisols.

Upper sola of Brunisolics occurring under tundra vegetation tend to be acidic with low base saturation. Several Brunisolic subgroups are intimately associated, as are soils from the Podzolic, Regosolic, and Gleysolic Orders. Further, under heath tundra vegetation, graying A horizons with characteristics of Ah and Ae horizons (herein termed Ahe horizons) often replace or coexist with Ah horizons. Conversely, soils associated with Subalpine grasslands and dry shrublands are less variable than those under tundra vegetation. Upper sola of grassland and shrubland Brunisolics tend to have a neutral reaction with a high base saturation. Consequently, Ae and Ahe horizons giving Eluviated subgroups are absent and also, Dystric and Sombric Brunisols and Podzolics do not occur. Regosolic soils, however, are common associates. There is evidence that some of the soils occurring under grassland vegetation can also be classed as Dark Brown in the Chernozemic Order. Subalpine grasslands and dry shrublands are most common in, but not confined to, the Front Ranges and are usually associated with genetic material derived from Mesozoic strata.

LUVISOLIC ORDER

Gray Luvisols occur in association with Eutric Brunisols showing luvisolic tendencies in warm, dry, lower portions of the Lower Subalpine and throughout much of the Montane. They commonly occur on calcareous glacial and glaciolacustrine materials with rapidly to moderately well drained moisture regimes, most often under lodgepole pine forests. They are identified by eluvial Ae and illuvial Bt horizons. Structure and clay film development are more weakly expressed in Bt horizons of Banff and Jasper Luvisolics than in much of the forested areas in Alberta. Most of the Luvisolic soils have *bisequa* morphology and are classed as Brunisolic Gray Luvisols.

They have an Ae–Bm horizon sequence developed in very thin veneers of Eolian material B overlying a II Bt horizon. Orthic Gray Luvisols occur where the veneer is absent. Gleyed Brunisolic Gray Luvisols, characterized by weak mottling in middle to lower sola and C horizons, occur occasionally on seepage affected (imperfectly drained), low lime till.

PODZOLIC ORDER

Podzolic soils represent the most strongly developed soils in Banff and Jasper. They are associated with Eutric/Melanic or Dystric/Sombric Brunisols under cool, moist Subalpine and Alpine conditions on stable landforms (usually morainal) that include veneers of Eolian material B or Fluviolacustrine material A derived from Eolian material B.

The Brunisolic–Podzolic complex of soils is most common in western Banff and southwestern Jasper. Reddish to dark brown podzolic B horizons (C.S.S.C. 1978b) are diagnostic of Podzolic soils. These develop immediately above the parent material disconformity and contain high amounts (>0.6%) of free iron and aluminum weathered from the iron and aluminum containing minerals within the surfical veneers. Orthic Humo–Ferric Podzols, with podzolic Bf horizons, occur at moderate elevations under well to moderately well drained conditions with Engelmann spruce–subalpine fir and subalpine larch forests. However, illuvial humus content in the podzolic B horizons tends to increase with elevation. Consequently, Orthic Ferro–Humic Podzols, with podzolic Bhf horizons, are common under heath tundra vegetation in the Alpine and Alpine–Upper Subalpine ecotone. Podzolic soils with podzolic Bf, Bhf, or Bh horizons also occur under imperfectly to poorly drained conditions in the Subalpine and Alpine Ecoregions on landforms (usually morainal) that include the Fluviolacustrine material A veneers.

CHERNOZEMIC ORDER

Steeply sloping, southerly–facing Subalpine grasslands and dry shrublands are dominated by Regosolic and Brunisolic soils with organo–mineral Ah surface horizons. There is some new evidence, based on soil temperature data from our instrumented Mt. White grassland site in Banff, that some of the Humic Regosols and Melanic Brunisols (soils with $\geq$ 10 cm of Ah horizon), may, in fact, be classed as Chernozemic. Morphological and chemical data support classification in the Dark Brown Great Group of the Chernozemic Order. Chernozemic soils are not reflected in the Banff–Jasper Ecological Land Classification map legend because the temperature data are tentative and these soils are of limited areal extent.

CRYOSOLIC ORDER

Cryosolic soils represent the coldest soils found in Banff and Jasper. They have permafrost within 1 m and often within 50 cm of the ground surface. Cryosolic soils dominate many steep (30–70%), northerly–facing, forested (Engelmann spruce–subalpine fir) slopes in the Upper Subalpine in the Front Ranges subprovince north of Banff townsite. They are confined primarily to morainal landforms consisting of medium textured, variably calcareous till derived from Mesozoic strata.

Regosolic Static Cryosols are most abundant. Their genesis is commonly influenced by solifluction which disrupts horizon development and mixes geomorphic material in the thaw zone. Orthic Static Cryosols and, occasionally, Brunisolic Static Cryosols occur on sites where the solifluction process is inconsequential. Cryosolics often have thick (10–40 cm) organic layers (LFH horizons) mantling the mineral surface and are generally imperfectly drained except for a saturated zone at the frozen–unfrozen interface. Gleyed Eutric Brunisols and Gleyed Cumulic Regosols are frequently associated with Cryosolic soils. Achuff and Coen (1980) present data from a Brunisolic Static Cryosol site on Mt. White in Banff.

REGOSOLIC ORDER

Regosolic soils occur where active and recently active geomorphic processes of sufficient frequency and intensity inhibit pedogenic horizonation other than Ah horizon formation. They occur in all Ecoregions, on a variety of calcareous and noncalcareous geomorphic materials, on a

variety of slopes, and under several different kinds of vegetation. Processes that modify landform surfaces and contribute to Regosolic soil maintenance are avalanching, soil creep, fluvial erosion and deposition, eolian deflation and deposition, windthrow of trees, sheet erosion, gully erosion, solifluction, and cryoturbation. Landforms of recent age also have Regosolic soils. These include recent moraines, glaciofluvial floodplains, colluvial slopes, landslides, fluvial landforms, and eolian deposits.

Regosolic soils lack significant B horizons. The Regosol Great Group lacks surface Ah horizons or has Ah horizons <10 cm thick. Humic Regosols have Ah horizons ≥ 10 cm in thickness and are common on avalanched localities, grasslands, dry shrublands, and under tundra vegetation in the Alpine and Alpine–Upper Subalpine ecotone. Cumulic Subgroups of these Great Groups have buried organic and organomineral horizons and, occasionally, buried B horizons. Gleyed and Gleyed Cumulic Subgroups occur under imperfectly to poorly drained conditions and are often associated with Gleysolic and, less often, Organic soils. Under drier conditions, Regosolic soils are most often associated with Brunisolic soils.

GLEYSOLIC ORDER

Gleysolic soils occur under imperfectly to poorly drained conditions on glacial, glaciolacustrine, fluvial, and fluviolacustrine landforms throughout all Ecoregions in Banff and Jasper. They generally occupy depressional landscapes where seepage, surface water collection, and high water tables are important and occur under a variety of moist to wet (hygric to hydric) vegetation. They are most often associated with gleyed Brunisolic, gleyed Podzolic, gleyed Regosolic, and Organic soils.

Gleysolic soils are characterized by dull colors and/or strong mottling within 50 cm of the mineral surface, features indicative of intense reducing conditions. Rego Gleysols occur on sites where saturation is prolonged or geomorphic activity has inhibited pedogenic horizonation. Orthic Gleysols occur on stable sites where B horizons have developed. Thin organic layers of moderately decomposed fen peat commonly mantle Gleysolic soils, except where mineral material is actively aggrading. Some Gleysolic soils have thin Ah horizons but Humic Gleysols (Ah horizons ≥ 10 cm thick) are of minor importance.

ORGANIC ORDER

Organic soils occur most often in association with Gleysolic soils under poorly to very poorly drained conditions, primarily on glacial, fluvial, and fluviolacustrine landforms. They are characterized by accumulations of 40 cm or more of fen peat. Prolonged periods of ponding, without mineral material sedimentation, and fen vegetation promote the accumulation of peat. Organic soils also occur on slopes of up to 15% where seepage is an important factor throughout much of the year.

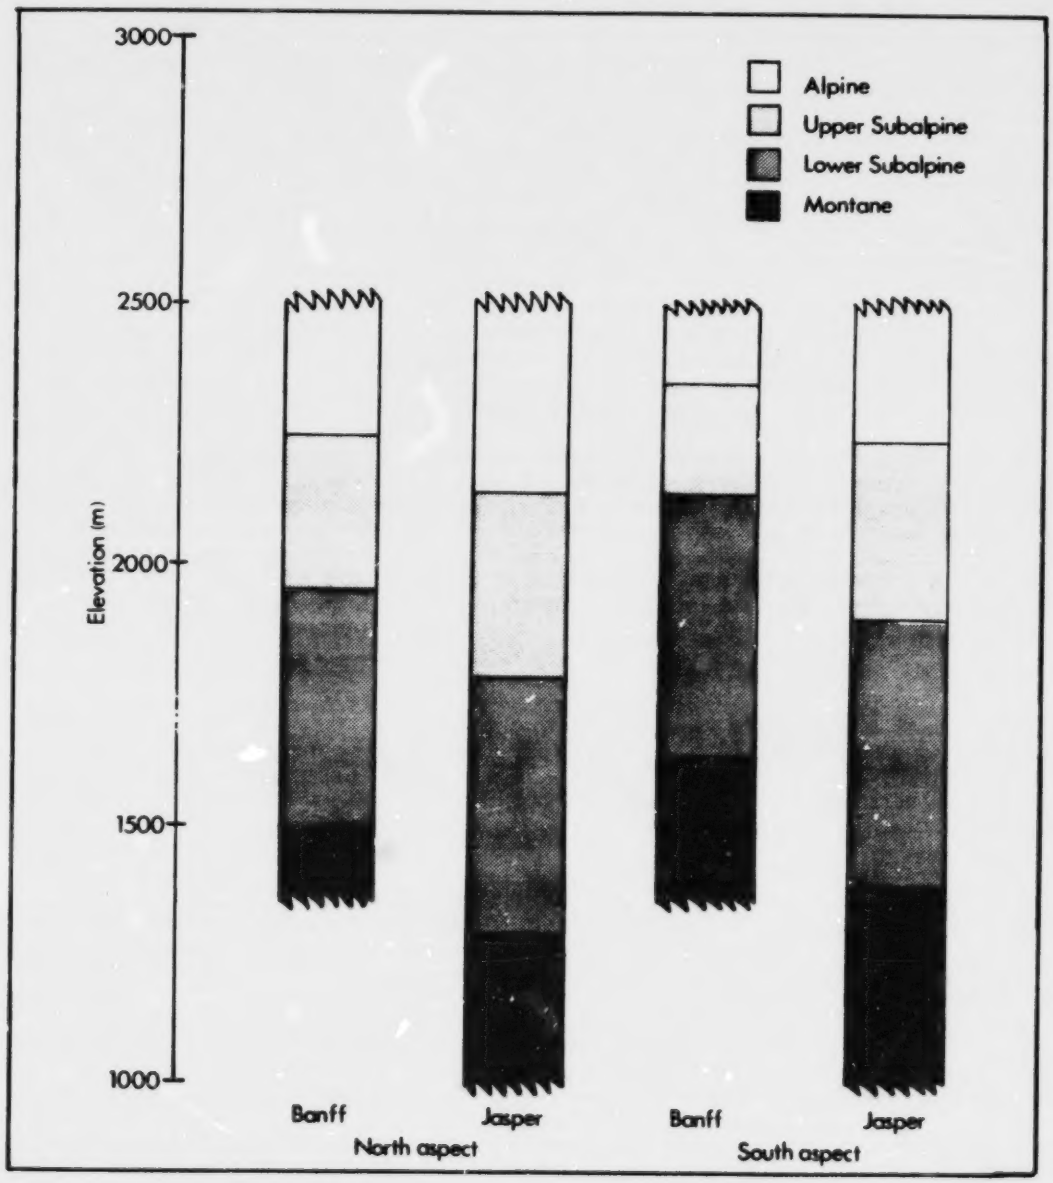
The peat is mainly moderately decomposed, hence the dominant Great Group is Mesisol. The peat accumulations rarely exceed 1.2 m in depth and the dominant Organic soils in Banff and Jasper are therefore Terric Mesisols.

VEGETATION

ECOREGIONS

Vegetation is used as the basis for definition of Ecoregions in the Ecological Land Classification. Ecoregional divisions reflect macroclimate and thus vegetational features (which primarily reflect climatic factors, rather than, for example, edaphic factors) are used to define the Ecoregions. From low to high elevation, three Ecoregions are recognized: Montane, Subalpine and Alpine (Fig. 6).

Fig. 6. Elevational ranges of Ecoregions and Ecoregion subunits in Banff and Jasper.



The Montane Ecoregion is characterized by v.t.s. dominated by Douglas fir (*Pseudotsuga menziesii*), white spruce (*Picea glauca*), and aspen poplar (*Populus tremuloides*), and by grasslands. Characteristic also is intermittent snow cover as a result of chinooks. The elevation of the Montane Ecoregion ranges from the lowest elevation in the parks (about 1350 m in Banff and 1000 m in Jasper) to about 1600 m in Banff and 1350 m in Jasper. This boundary is slightly lower on northerly aspects and slightly higher on southerly aspects.

The Subalpine Ecoregion occurs at altitudes above the Montane Ecoregion and below the unforested Alpine Ecoregion. The Subalpine Ecoregion is further divided into Lower Subalpine and Upper Subalpine portions. The predominant vegetation of the Lower Subalpine is closed coniferous forest. Mature forest is dominated by Engelmann spruce (*Picea engelmannii*) and subalpine fir (*Abies lasiocarpa*). Seral lodgepole pine (*Pinus contorta*) forests are common, especially at lower altitudes. The upper altitudinal boundary of the Lower Subalpine is generally about 2000 m in Banff and 1900 m in Jasper. The Upper Subalpine portion is broadly transitional between Lower Subalpine closed forest and treeless Alpine tundra. Compared to the Lower Subalpine, the Upper Subalpine is cooler and wetter, with greater snowfall, later snow melt, and a shorter growing season. Greater wind speed also appears to be a significant factor. Perhaps most characteristic are open forests and stunted tree growth forms (krummholz). Upper Subalpine closed forests typically contain some Alpine floristic elements. In southern Banff, forests containing subalpine larch (*Larix lyallii*) are characteristic of the Upper Subalpine. Lodgepole pine is generally absent and forests are usually dominated by Engelmann spruce and subalpine fir. The upper altitudinal boundary to the Alpine Ecoregion is about 2300 m in Banff and 2200 m in Jasper.

The treeless Alpine Ecoregion occurs at altitudes above the Upper Subalpine and reflects a cold, harsh climate. Alpine vegetation typically forms a complex, fine-scale mosaic in which microclimatic variations are reflected by marked changes in dominant species and v.t.s. Significant microclimatic factors include: aspect, wind exposure, time of snow melt, soil moisture, and snow depth. Dwarf shrub tundra dominated by yellow heather (*Phyllodoce glanduliflora*) and white mountain heather (*Cassiope mertensiana*) is characteristic of lower altitudes, while the highest altitude communities are usually dominated by lichens and occur on rocky shallow soil.

SUCCESSION AND CLIMAX

Succession deals with changes in vegetation through time. Primary succession occurs on sites without previous vegetation, such as newly deposited fluvial or morainal material, and may require more than a thousand years to reach a climax stage. Secondary succession occurs on sites which have been previously vegetated but have had the vegetation removed, as by fire. Secondary successions take less time than primary succession, with hundreds of years being typical.

Secondary succession following fire is the most common situation in Banff and Jasper and nearly all of the present forest has been subject to fire. For example, the Athabasca River Valley around Jasper townsite experienced major fires (>500 ha) in 24 of the years between 1665 and 1975, with most of the present forest originating after fires in 1889, 1847 and 1758 (Tande 1977). The potential complexity of successional relationships has been greatly simplified by a peak in fire frequency 100 to 120 years ago. This has resulted in the bulk of the lodgepole pine forests being in approximately the same successional stage. Earlier, preclimax stages are comparatively rare and areas of recent burn are limited, e.g. Survey Peak–Saskatchewan River Crossing and Flint's Park in Banff, lower Chaba River in Jasper.

A four stage successional sequence was used to classify v.t.s. in this report: early, intermediate, advanced and mature (climax). The early successional stage is usually heterogeneous and unstable in composition, often not referable to a v.t. and usually less than 50 years old since major disturbance or origin. The intermediate successional stage is moderately stable, more uniform in composition and dominated by species not climax for the site. Commonly, lodgepole pine dominates but Engelmann spruce and subalpine fir regeneration in the understory indicates an eventual dominance by these two species. Successionally intermediate communities are

generally 50 to 100 years old, although considerable variation occurs. Advanced successional communities are generally 80 to 200 years old and are dominated by a mixture of successional and climax species. In forested v.t.s., this is most typically a mixture of lodgepole pine (successional) and Engelmann spruce or subalpine fir (climax). The duration of this stage varies but 40 to 50 years is typical. The mature (climax) stage is stable, self-perpetuating and the end point of vegetation succession. In Banff and Jasper it generally takes 100 to 200 years to reach this stage in forest communities following initiation by fire.

In the Montane Ecoregion, mature forests are generally dominated by Douglas fir and white spruce which have often developed from lodgepole pine forests. However, on some dry sites, lodgepole pine forms climax forests. On the driest Montane sites, grasslands form the mature vegetation. Fire appears to be important in maintaining these grasslands and return to a climax condition following fire may take only ten years. Mature forests in the Subalpine Ecoregion are dominated by Engelmann spruce and subalpine fir which have often succeeded lodgepole pine forests. In the Upper Subalpine where lodgepole pine is less common, spruce and fir may be the initial tree colonizers after fire and a pine stage may be absent. Succession is slower in the Upper Subalpine, often requiring more than 250 years to reach a mature stage. Succession in the treeless Alpine Ecoregion is more difficult to document than in forests where tree ages provide easily obtained evidence of stand age. Fire is infrequent in the Alpine and water erosion and cryogenic processes are the main agents of disturbance which initiate secondary succession. Succession is very slow and recovery after trampling may take hundreds of years (Willard and Marr 1971).

Succession in wetlands differs from that on uplands. The rates appear to be slower although the usual herbaceous or shrubby vegetation makes stand history determination difficult. Since most wetland v.t.s. appear to be relatively stable over a 50 to 100 year period they have been designated successionally mature in this report. Landscape changes due to peat accumulation, stream aggradation and erosion, and cryoturbation are often coincident with vegetational succession on these sites, thus confounding successional history determination.

VEGETATION TYPE DESCRIPTIONS

This section contains abbreviated descriptions of 85 v.t.s., including both environmental characteristics and characteristic species with their typical cover values. The descriptions are arranged by physiognomic class: Closed Forest (C), Open Forest (O), Shrub (S), Low Shrub-Herb (L), and Herb-Dwarf Shrub (H), and numerically within each class (C1, C2, etc). More complete descriptions are in Volume II of this report.

CLOSED FOREST VEGETATION TYPES

C1: *Pseudotsuga menziesii/Elymus innovatus*
(Douglas fir/hairy wild rye)

Environment

Ecoregion: Montane
Moisture Regime: subxeric
Soils: Eutric Brunisols, Regosolics
Slope: moderate-steep
Aspect: southerly
Landform: colluvial, morainal

Characteristic Species (% cover)

Trees
Pseudotsuga menziesii 30-40

Shrubs

Juniperus communis	1–15	*Shepherdia canadensis*	1–5

Herbs–Dwarf Shrubs

Calamagrostis rubescens	10–35	*Fragaria virginiana*	<5
Elymus innovatus	5–20	*Achillea millefolium*	<5
Aster conspicuus	5–10	*Arctostaphylos uva-ursi*	<5

Bryoids

Hylocomium splendens	<1	*Peltigera aphthosa*	<1

Successional Status: mature
Related Vegetation Types: C5

C2: *Picea glauca/Thuidium abietinum*
(white spruce/fern moss)

Environment

Ecoregion: Montane
Moisture Regime: mesic
Soils: Cumulic Regosols, Eutric Brunisols
Slope: various
Aspect: northerly
Landform: eolian, fluvial

Characteristic Species (% cover)

Trees

Picea glauca	15–60

Shrubs

Rosa acicularis	<5	*Shepherdia canadensis*	<3

Herbs–Dwarf Shrubs

Elymus innovatus	1–10	*Pyrola secunda*	<3
Linnaea borealis	1–8		

Bryoids

Thuidium abietinum	20–95	*Hylocomium splendens*	<15

Successional Status: advanced–mature
Related Vegetation Types: C13, C26, C27, C37

C3: *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi*
(lodgepole pine/juniper/bearberry)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: subxeric–mesic
Soils: Eutric Brunisols, Regosolics
Slope: various
Aspect: southerly, westerly
Landform: morainal, colluvial, fluvial, glacio–fluvial

Characteristic Species (% cover)

Trees

Pinus contorta	15–40

Shrubs			
Juniperus communis	5-25	*Shepherdia canadensis*	5-15
Rosa acicularis	1-3		
Herbs-Dwarf Shrubs			
Arctostaphylos uva-ursi	10-25	*Linnaea borealis*	3-8
Elymus innovatus	5-15	*Fragaria virginiana*	<1
Solidago decumbens	<1	*Hedysarum sulphurescens*	<1
Bryoids			
Pleurozium schreberi	<1	*Drepanocladus uncinatus*	<1
Hylocomium splendens	<1	*Dicranum* spp.	<1
Epiphytes			
Letharia vulpina			

Successional Status: advanced-mature
Related Vegetation Types: C6, C9, C19

C4: *Picea glauca/Rosa acicularis/Equisetum arvense*
(white spruce/prickly rose/horsetail)

Environment

Ecoregion: Montane
Moisture Regime: subhygric-hygric
Soils: Gleysolics, Regosolics, Organics
Slope: gentle
Aspect: various
Landform: fluvial

Characteristic Species (% cover)

Trees			
Picea glauca	20-55		
Shrubs			
Rosa acicularis	5-15	*Cornus stolonifera*	3
Alnus tenuifolia	5	*Ribes lacustre*	1
Herbs-Dwarf Shrubs			
Equisetum arvense	30-50	*Equisetum pratense*	5-15
Linnaea borealis	5	*Mitella nuda*	1
Equisetum scirpoides	5	*Pyrola asarifolia*	<1
Bryoids			
Hylocomium splendens	15-50		

Successional Status: mature
Related Vegetation Types: C32

C5: *Picea glauca-Pseudotsuga menziesii/Hylocomium splendens*
(white spruce-Douglas fir/feathermoss)

Environment

Ecoregion: Montane-Lower Subalpine
Moisture Regime: mesic
Slope: various
Aspect: northerly

Soils: Eutric Brunisols, Regosolics, Gray Luvisols

Landform: fluvial, morainal

Characteristic Species (% cover)

Trees			
Picea glauca	20–40	*Pseudotsuga menziesii*	20–40
Shrubs			
Rosa acicularis	<1	*Shepherdia canadensis*	<1
Herbs–Dwarf Shrubs			
Pyrola secunda	<1	*Linnaea borealis*	<5
Aster conspicuus	<5	*Cornus canadensis*	<5
Elymus innovatus	<3		
Bryoids			
Hylocomium splendens	30–75	*Peltigera aphthosa*	3–5
Pleurozium schreberi	<1	*Ptilium crista-castrensis*	<1
Epiphytes			
Letharia vulpina		*Parmelia sulcata*	

Successional Status: mature
Related Vegetation Types: C1

C6: *Pinus contorta/Shepherdia canadensis/Aster conspicuus*
(lodgepole pine/buffaloberry/showy aster)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: mesic
Soils: Eutric Brunisols, Regosolics, Gray Luvisols

Slope: moderate
Aspect: southerly, westerly
Landform: morainal, fluvial, colluvial, glaciofluvial

Characteristic Species (% cover)

Trees			
Pinus contorta	25–45	*Picea* spp.	<10
Shrubs			
Shepherdia canadensis	15–30	*Juniperus communis*	1–5
Rosa acicularis	10–20	*Spiraea lucida*	1
Herbs–Dwarf Shrubs			
Aster conspicuus	10–20	*Elymus innovatus*	10–15
Linnaea borealis	3–5	*Arctostaphylos uva-ursi*	1–3
Arnica cordifolia	1–5	*Calamagrostis rubescens*	10–20
Bryoids			
Hylocomium splendens	10–30	*Pleurozium schreberi*	10–25
Peltigera aphthosa	1–3		
Epiphytes			
Letharia vulpina		*Alectoria* spp.	
Usnea spp.			

Successional Status: intermediate–advanced
Related Vegetation Types: C3, C9, C18, C19

C8: *Picea mariana–Pinus contorta/Salix myrtillifolia/Carex vaginata*
(black spruce–lodgepole pine/willow/sedge)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: hygric
Soils: Gleysolics, Organics

Slope: level–gentle
Aspect: northerly
Landform: morainal

Characteristic Species (% cover)

Trees			
Picea mariana	10–40	*Pinus contorta*	5–10
Shrubs			
Salix myrtillifolia	5–10	*Ledum groenlandicum*	5–20
Herbs–Dwarf Shrubs			
Carex vaginata	2–5	*Carex capillaris*	1
Arctostaphylos rubra	3	*Petasites palmatus*	<1
Equisetum arvense	<1	*Equisetum scirpoides*	<1
Bryoids			
Aulacomnium palustre	5–30	*Tomenthypnum nitens*	5
Hylocomium splendens	10–50	*Pleurozium schreberi*	5–20
Peltigera aphthosa	<1		

Successional Status: advanced–mature
Related Vegetation Types: O11

C9: *Pinus contorta/Vaccinium caespitosum*
(lodgepole pine/dwarf bilberry)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: mesic–subxeric
Soils: Eutric and Dystric Brunisols, Gray Luvisols

Slope: level
Aspect: southerly
Landform: fluvial, glaciofluvial, glaciolacustrine

Characteristic Species (% cover)

Trees			
Pinus contorta	25–40		
Shrubs			
Shepherdia canadensis	6	*Rosa acicularis*	1
Juniperus communis	1		
Herbs–Dwarf Shrubs

OPEN FOREST VEGETATION TYPES

O2: *Pinus flexilis–Pseudotsuga menziesii/Juniperus* spp./*Arctostaphylos uva-ursi*
(limber pine–Douglas fir juniper/bearberry)

Environment

Ecoregion: Montane
Moisture Regime: xeric–subxeric
Soils: Regosolics

Slope: moderate–steep
Aspect: southerly
Landform: glacial

Characteristic Species (% cover)

Trees			
Pinus flexilis	5–40	*Pseudotsuga menziesii*	10–15
Shrubs			
Juniperus scopulorum	15–20	*Juniperus communis*	5–10
Potentilla fruticosa	<2		
Herbs–Dwarf Shrubs			
Arctostaphylos uva-ursi	20	*Artemisia frigida*	<5
Erigeron caespitosus	<4	*Anemone patens*	<3
Oxytropis sericea	<2		

Successional Status: mature
Related Vegetation Types: O5

O3: *Picea glauca/Potentilla fruticosa/Arctostaphylos uva-ursi*
(white spruce/shrubby cinquefoil/bearberry)

Environment

Ecoregion: Montane
Moisture Regime: subxeric–mesic
Soils: Regosolics

Slope: level–gentle
Aspect: various
Landform: fluvial

Characteristic Species (% cover)

Trees			
Picea glauca	5–20		
Shrubs			
Potentilla fruticosa	1–15	*Shepherdia canadensis*	1–10
Juniperus communis	<10		
Herbs–Dwarf Shrubs			
Arctostaphylos uva-ursi	5–35	*Elymus innovatus*	1–30
Fragaria virginiana	1–3		
Bryoids			
Thuidium abietinum	1–10	*Ditrichum flexicaule*	<3
Peltigera canina	<1		

Successional Status: intermediate–mature
Related Vegetation Types: O17

O4: *Picea engelmannii–Abies lasiocarpa–Pinus albicaulis–Pinus contorta*
(Engelmann spruce–subalpine fir–whitebark pine–lodgepole pine)

Environment

Ecoregion: Lower–Upper Subalpine
Moisture Regime: subxeric
Soils: Eutric and Dystric Brunisols, Regosolics

Slope: steep
Aspect: southerly
Landform: colluvial, morainal

Characteristic Species (% cover)

Trees			
Picea engelmannii	<20	*Abies lasiocarpa*	<20
Pinus albicaulis	<20	*Pinus contorta*	<20
Shrubs			
Juniperus communis	3–20	*Shepherdia canadensis*	<15
Herbs–Dwarf Shrubs			
Elymus innovatus	3–15	*Arctostaphylos uva-ursi*	3–25
Linnaea borealis	<10	*Zygadenus elegans*	<3
Fragaria virginiana	<10		

Successional Status: intermediate–mature
Related Vegetation Types: C3, O10

O5: *Pseudotsuga menziesii/Juniperus communis/Arctostaphylos uva-ursi*
(Douglas fir/juniper/bearberry)

Environment

Ecoregion: Montane
Moisture Regime: subxeric–xeric
Soils: Regosolics, Eutric Brunisols
Slope: moderate–steep
Aspect: southerly
Landform: glacial

Characteristic Species (% cover)

Trees			
Pseudotsuga menziesii	5–25	*Picea glauca*	<5
Shrubs			
Juniperus communis	5–15	*Pseudotsuga menziesii*	5–25
Rosa acicularis	<2	*Spiraea lucida*	≤1
Herbs–Dwarf Shrubs

Slope: gentle-steep
Aspect: northerly
Landform: morainal, colluvial

Characteristic Species (% cover)

Herbs-Dwarf Shrubs			
Cassiope tetragona	10-50	*Phyllodoce glanduliflora*	<15
Dryas octopetala	10-35	*Salix nivalis*	10-35
Polygonum viviparum	<1	*Silene acaulis*	<5
Potentilla diversifolia	1	*Salix arctica*	<15
Bryoids			
Dicranum scoparium	<2	*Cetraria islandica*	<5
Cetraria nivalis	<3	*Stereocaulon alpinum*	<3

Successional Status: mature
Related Vegetation Types: C23, O10, L5, H1

L5: *Phyllodoce glanduliflora-Cassiope mertensiana-Antennaria lanata*
(heather-everlasting)

Environment

Ecoregion: Alpine
Moisture Regime: mesic
Soils: Brunisolics, Humo-Ferric Podzols
Slope: various
Aspect: various
Landform: morainal, residual

Characteristic Species (% cover)

Herbs-Dwarf Shrubs			
Phyllodoce glanduliflora	10-50	*Cassiope mertensiana*	10-70
Cassiope tetragona	<10	*Antennaria lanata*	2-15
Salix arctica	<15	*Sibbaldia procumbens*	<5
Erigeron peregrinus	<2	*Potentilla diversifolia*	<1
Luzula wahlenbergii	1	*Artemisia norvegica*	<5
Bryoids			
Dicranum scoparium	<10	*Polytrichum juniperinum*	<3
Cladonia ecmocyna	<3	*Cetraria islandica*	<2

Successional Status: mature
Related Vegetation Types: C23, O10, L4

L6: *Juniperus horizontalis–Agropyron dasystachyum–Carex scirpoidea*
(creeping juniper–northern wheatgrass–sedge)

Environment

Ecoregion: Montane
Moisture Regime: subxeric
Soils: Regosolics

Slope: various
Aspect: southerly
Landform: eolian

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Juniperus horizontalis	20–30	*Agropyron dasystachyum*	5–10
Carex scirpoidea	5–30	*Potentilla fruticosa*	<5
Hedysarum mackenzii	<5	*Arctostaphylos uva-ursi*	<5
Koeleria cristata	<5	*Senecio cymbalarioides*	<1
Carex richardsonii	<1		

Successional Status: mature
Related Vegetation Types: H6, H7

L7: *Salix arctica–Potentilla diversifolia*
(arctic willow–cinquefoil)

Environment

Ecoregion: Upper Subalpine–Alpine
Moisture Regime: mesic–subhygric
Soils: Regosolics, Gleysolics, Brunisolics

Slope: various
Aspect: various
Landform: morainal, fluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Salix arctica	10–35	*Potentilla diversifolia*	1–3
Antennaria lanata	5–20	*Phyllodoce glanduliflora*	1–5
Salix nivalis	1–5	*Castilleja occidentalis*	1–3
Erigeron peregrinus	<1	*Poa alpina*	<1
Polygonum viviparum	<1	*Sibbaldia procumbens*	<1
Artemisia norvegica	<1		
Bryoids			
Cladonia pyxidata	<1	*Cetraria ericetorum*	<1
Cetraria cucullata	<1		

Successional Status: mature
Related Vegetation Types: H2, H16

HERB-DWARF SHRUB VEGETATION TYPES

H1: *Dryas octopetala–Salix nivalis–Silene acaulis*
(mountain avens–snow willow–moss campion)

Environment

Ecoregion: Alpine
Moisture Regime: mesic–subxeric
Soils: Regosolics, Brunisolics

Slope: various
Aspect: southerly, westerly
Landform: morainal, colluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Dryas octopetala	20–50	*Salix nivalis*	1–10
Silene acaulis	1–3	*Oxytropis podocarpa*	<3
Polygonum viviparum	1–2	*Selaginella densa*	<1
Poa alpina	<1	*Potentilla diversifolia*	<1
Salix arctica	<1	*Castilleja occidentalis*	<1
Carex nardina	<1	*Saxifraga oppositifolia*	<1
Bryoids			
Cetraria nivalis	<1	*Cetraria cucullata*	<1

Successional Status: mature
Related Vegetation Types: L4, L5, L7, H2, H4

H2: *Carex nigricans–Antennaria lanata*
(black alpine sedge–everlasting)

Environment

Ecoregion: Alpine
Moisture Regime: mesic–subhygric
Soils: Dystric and Sombric Brunisols, Humo–Ferric Podzols
Slope: various
Aspect: various
Landform: morainal, residual

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Carex nigricans	10–90	*Antennaria lanata*	5–35
Luzula wahlenbergii	<5	*Sibbaldia procumbens*	<5
Veronica alpina	<3	*Juncus drummondii*	<5
Poa alpina	<10	*Ranunculus eschscholtzii*	<5
Salix arctica	<12	*Phyllodoce glanduliflora*	<10
Bryoids			
Pogonatum alpinum	2–20	*Tortula norvegica*	<2
Cladonia ecmocyna	<5		

Successional Status: mature
Related Vegetation Types: L4, L5, L7, H1

H3: *Carex scirpoidea–Saxifraga aizoides*
(sedge–saxifrage)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: hygric
Soils: Gleysolics
Slope: level
Aspect: various
Landform: fluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Carex scirpoidea	1–5	*Saxifraga aizoides*	1–5
Anemone parviflora	1–3	*Tofieldia pusilla*	<3
Polygonum viviparum	<1	*Equisetum variegatum*	<1
Castilleja occidentalis	<1	*Dryas integrifolia*	<1
Arctostaphylos rubra	<1	*Pinguicula vulgaris*	<1
Potentilla fruticosa	<1	*Saxifraga* sp.	<1

Successional Status: early–intermediate
Related Vegetation Types: S7

H4: *Dryas octopetala–Kobresia myosuroides–Arctostaphylos uva-ursi*
(mountain avens–kobresia–bearberry)

Environment

Ecoregion: Upper Subalpine–Alpine
Moisture Regime: subxeric–mesic
Soils: Melanic and Eutric Brunisols, Humic Regosolics
Slope: moderate–steep
Aspect: southerly
Landform: morainal, colluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Dryas octopetala	10–35	*Arctostaphylos uva-ursi*	5–30
Kobresia myosuroides	15–40	*Polygonum viviparum*	<5
Oxytropis podocarpa	<15	*Androsace chamaejasme*	<3
Silene acaulis	<2		
Bryoids			
Cetraria nivalis	<10	*Cetraria cucullata*	<10

Successional Status: mature
Related Vegetation Types: H1, H5, H14

H5: *Elymus innovatus–Fragaria virginiana–Epilobium angustifolium*
(hairy wild rye–wild strawberry–fireweed)

Environment

Ecoregion: Upper Subalpine
Moisture Regime: mesic
Soils: Melanic Brunisols, Humic Regosols
Slope: steep
Aspect: southerly
Landform: colluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Elymus innovatus	15–55	*Fragaria virginiana*	1–10
Myosotis alpestris	<10	*Epilobium angustifolium*	<10
Zygadenus elegans	<8	*Achillea millefolium*	<5
Salix spp.	<5	*Rosa acicularis*	<5

Successional Status: mature
Related Vegetation Types: H6, H7, H14, H16, S2

H6: *Koeleria cristata–Artemisia frigida–Linum lewisii*
(junegrass–pasture sage–wild blue flax)

Environment

Ecoregion: Montane
Moisture Regime: subxeric–xeric
Soils: Regosolics, Eutric Brunisols
Slope: level–moderate
Aspect: southerly
Landform: fluvial, glaciofluvial, eolian

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Koeleria cristata	15–30	*Artemisia frigida*	1–20
Linum lewisii	1–10	*Antennaria nitida*	1–10
Galium boreale	<5	*Senecio cymbalarioides*	1–5
Gaillardia aristata	<5		
Bryoids			
Tortula ruralis	<3		

Successional Status: mature
Related Vegetation Types: H7, H13, H14

H7: *Agropyron dasystachyum–Artemisia frigida*
(wheatgrass–pasture sage)

Environment

Ecoregion: Montane
Moisture Regime: xeric
Soils: Eutric Brunisols, Regosolics
Slope: steep
Aspect: southerly
Landform: colluvial, glacial, fluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Agropyron dasystachyum	5–50	*Artemisia frigida*	1–10
Koeleria cristata	2–10	*Achillea millefolium*	<5

Successional Status: mature
Related Vegetation Types: H6, H13, H14

H8: *Dryas drummondii–Epilobium latifolium*
(yellow dryad–willow herb)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: subxeric–subhygric
Soils: Regosolics
Slope: gentle
Aspect: various
Landform: fluvial, glaciofluvial, morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Dryas drummondii	25–80	*Shepherdia canadensis*	<10
Salix brachycarpa	<15	*Arctostaphylos uva-ursi*	<5
Epilobium latifolium	<2		

Bryoids			
Drepanocladus uncinatus	<3	*Tortula norvegica*	<10

Successional Status: early
Related Vegetation Types: O3, S7, H3

H9: *Caltha leptosepala–Trollius albiflorus*
(mountain marigold–globeflower)

Environment

Ecoregion: Upper Subalpine–Alpine
Moisture Regime: subhygric–hygric
Soils: Gleysolics

Slope: gentle–moderate
Aspect: northerly, easterly
Landform: fluvial, morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Caltha leptosepala	10–25	*Trollius albiflorus*	15–40
Carex nigricans	5–20	*Salix arctica*	5–10
Senecio triangularis	<10	*Erigeron peregrinus*	<10
Antennaria lanata	<10	*Pedicularis bracteosa*	<5
Polygonum viviparum	<5	*Valeriana sitchensis*	<5
Bryoids			
Aulacomnium palustre	10–50	*Campylium stellatum*	<10

Successional Status: mature
Related Vegetation Types: H2, H10, H16

H10: *Eriophorum angustifolium–Drepanocladus* spp.
(cottongrass/moss)

Environment

Ecoregion: Upper Subalpine
Moisture Regime: hydric
Soils: Gleysolics, Organics

Slope: gentle
Aspect: various
Landform: fluvial, morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Eriophorum angustifolium	20–60	*Caltha leptosepala*	variable
Carex nigricans	var.	*Pedicularis groenlandica*	variable
Scirpus caespitosus	var.		
Bryoids			
Drepanocladus exannulatus	70–80	*Drepanocladus revolvens*	variable
Calliergon sarmentosum	var.	*Paludella squarrosa*	variable

Successional Status: mature
Related Vegetation Types: H9, H16

H11: *Carex aquatilis–Carex rostrata*
(water sedge–beaked sedge)

Environment

Ecoregion: Montane–Upper Subalpine
Moisture Regime: hydric–subhydric
Soils: Organics, Gleysolics

Slope: level
Aspect: level
Landform: fluvial, morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Carex aquatilis	15–70	*Carex rostrata*	10–60
Equisetum fluviatile	20–55	*Utricularia intermedia*	<4
Lemna minor	<1		
Bryoids			
Drepanocladus revolvens	10–55	*Tomenthypnum nitens*	<35
Campylium stellatum	<15	*Bryum pseudotriquetrum*	<10

Successional Status: mature
Related Vegetation Types: S1, S7

H12: Saxicolous lichen

Environment

Ecoregion: Alpine
Moisture Regime: subxeric–xeric
Soils: Regosolics, nonsoil

Slope: various
Aspect: various
Landform: colluvial, bedrock

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Silene acaulis	<1	*Saxifraga oppositifolia*	<1
Selaginella densa	<1	*Oxytropis podocarpa*	<1
Draba incerta	<1	*Salix nivalis*	<1
Bryoids			
Xanthoria elegans	<1	*Rhizocarpon geographicum*	<1
Cetraria tilesii	<1	*Sporastatia testudinea*	<1
Cetraria nivalis	<1	*Acarospora chlorophana*	<1
Cladonia pyxidata	<1	*Dactylina ramulosa*	<1

Successional Status: mature
Related Vegetation Types: H1

H13: *Stipa richardsonii–Koeleria cristata–Antennaria nitida*
(Richardson needlegrass–junegrass–everlasting)

Environment

Ecoregion: Montane
Moisture Regime: subxeric–xeric
Soils: Regosolics, Eutric Brunisols

Slope: level–gentle
Aspect: southerly
Landform: glaciofluvial, fluvial, colluvial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Stipa richardsonii	5–20	*Koeleria cristata*	2–10
Antennaria nitida	<8	*Anemone multifida*	<5
Selaginella densa	5	*Penstemon confertus*	<3
Galium boreale	<2	*Festuca scabrella*	<1

Successional Status: mature
Related Vegetation Types: H6, H7, H14

H14: *Elymus innovatus–Koeleria cristata–Arctostaphylos uva-ursi*
(hairy wild rye–junegrass–bearberry)

Environment

Ecoregion: Lower–Upper Subalpine
Moisture Regime: subxeric
Soils: Melanic and Eutric Brunisols

Slope: steep
Aspect: southerly
Landform: colluvial, morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Elymus innovatus	5–50	*Hedysarum sulphurescens*	5–15
Koeleria cristata	5–35	*Arctostaphylos uva-ursi*	5–20
Bromus pumpellianus	1–10	*Achillea millefolium*	1–2
Fragaria virginiana	<10	*Anemone multifida*	<10
Cerastium arvense	<10	*Oxytropis splendens*	1
Myosotis alpestris	1–5	*Campanula rotundifolia*	<3
Antennaria nitida	1–2	*Poa* spp.	
Bryoids			
Tortula ruralis	<5		

Successional Status: mature
Related Vegetation Types: H4, H5, H6, H7, H13

H15: *Dryas integrifolia–Carex rupestris*
(mountain avens–curly sedge)

Environment

Ecoregion: Upper Subalpine
Moisture Regime: subhygric
Soils: Eutric Brunisols, Regosolics

Slope: steep
Aspect: easterly
Landform: morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Dryas integrifolia	10	*Carex rupestris*	20
Carex scirpoidea	3	*Carex albo-nigra*	3
Cassiope tetragona	3	*Ledum groenlandicum*	2
Arctostaphylos rubra	1		
Bryoids			
Cetraria sp.	<1		

Successional Status: mature
Related Vegetation Types: H1

H16: *Erigeron peregrinus–Valeriana sitchensis*
(fleabane–valerian)

Environment

Ecoregion: Upper Subalpine
Moisture Regime: subhygric–mesic
Soils: Dystric Brunisols, Gleysolics, Regosolics

Slope: various
Aspect: various
Landform: fluvial, morainal

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Erigeron peregrinus	5–20	*Valeriana sitchensis*	5–20
Trollius albiflorus	5–20	*Anemone occidentalis*	5–15
Senecio triangularis	1–10	*Antennaria lanata*	1–5
Artemisia norvegica	1–5	*Pedicularis bracteosa*	<1–3
Salix arctica	1–5	*Potentilla diversifolia*	<1–2
Carex nigricans	<1	*Sibbaldia procumbens*	<1
Phleum alpinum	<1		
Bryoids			
Tortula ruralis	<15	*Pseudoleskea radicosa*	<15

Successional Status: mature
Related Vegetation Types: L7, H2, H9

H19: *Agropyron spicatum–Elymus innovatus–Aster conspicuus*
(bluebunch wheatgrass–hairy wild rye–showy aster)

Environment

Ecoregion: Montane–Lower Subalpine
Moisture Regime: xeric
Soils: Regosolics

Slope: steep
Aspect: southerly
Landform: colluvial, glacial

Characteristic Species (% cover)

Herbs–Dwarf Shrubs			
Agropyron spicatum	15–30	*Elymus innovatus*	10–30
Koeleria cristata	3–10	*Aster conspicuus*	3–5
Oxytropis splendens	<8	*Antennaria nitida*	<2
Cerastium arvense	<2		

Successional Status: mature
Related Vegetation Types: H4, H5, H6, H7, H13, H14

H20: *Saxifraga bronchialis–Elymus innovatus*
(spotted saxifrage–hairy wild rye)

Environment

Ecoregion: Upper Subalpine
Moisture Regime: subxeric–xeric
Soils: Regosolics

Slope: steep
Aspect: southerly
Landform: colluvial

Characteristic Species (% cover)

(cover is variable for all species, with total cover usually <50%)

Herbs--Dwarf Shrubs

Saxifraga bronchialis
Potentilla nivea
Festuca saximontana
Elymus innovatus
Achillea millefolium
Zygadenus elegans

Bryoids

Tortula ruralis

Successional Status: mature
Related Vegetation Types: H12

KEY TO VEGETATION TYPES

USE OF THE KEY

The term *dominant* (species with the highest % cover) is used in the key, but *abundant* can usually be substituted. Occasionally, species other than those in the key leads may be dominant. In such cases, use the species in the key leads which is most abundant. For example, in a *Pinus contorta/Shepherdia canadensis* closed forest (lead 8) *Elymus innovatus* (35%) may be dominant with *Linnaea borealis* (5%), *Aster conspicuus* (2%) and *Vaccinium scoparium* (25%). *Elymus innovatus* is dominant but not in the key leads. Therefore, use the most abundant species which is in the leads, which is *Vaccinium scoparium* and the stand keys to C18.

The following general cover value terms are used but should not be rigidly interpreted: sparse <15%, moderate 15–50%, and dense >50%. Often the cover of a species relative to other species in the stand is a better guide to its significance than the absolute cover values. Polychotomous leads have been used to save space and simplify the key. Alternative leads are grouped to minimize confusion.

Not all stands will key to a v.t.; intermediates occur and heterogeneous stands may be virtually unclassifiable, although their affinities may be apparent. The descriptions contain additional information and comments on related v.t.s which will help better place the stand in question. The key is only an aid to classification. Always consult the v.t. description to validate the determination.

KEY TO PHYSIOGNOMIC GROUPS

1a. Vegetation with trees $\geq$ 5m tall and tree cover >5 % 2
1b. Vegetation without trees $\geq$5m tall or tree cover <5 % 3
2a. Distance between tree crowns < 2X crown width, total tree cover usually >20% (some Open Forest stands with 15–20% tree cover may key here) ..... Closed Forest(C), I
2b. Distance between tree crowns 2–5X crown width, total tree cover usually $\leq$20%, (some sparse Closed Forest stands with <20% cover may key here) ..... Open Forest(O), II
3a. Vegetation dominated by shrubs $\geq$0.5–5m tall ..... Shrub(S), III
3b. Vegetation dominated by plants $\leq$0.5m tall 4
4a. Vegetation dominated by low shrubs (0.1–0.5m tall) and herbs ..... Low Shrub(L), IV
4b. Vegetation dominated by dwarf shrubs (<0.1m tall) or herbs ..... Herb–Dwarf Shrub(H), V

I. KEY TO CLOSED FOREST VEGETATION TYPES

1a.	Dominant trees broad-leaved	2
1b.	Dominant trees needle-leaved	5
2a.	Dominant tree *Populus tremuloides*	3
2b.	Dominant tree *Populus balsamifera*	4
3a.	*Lathyrus ochroleucus* and *Galium boreale* > *Aster conspicuus*, landform fluvial	C16
3b.	*Aster conspicuus* > *Lathyrus ochroleucus* and *Galium boreale*, landform colluvial	C22
4a.	*Shepherdia canadensis* and *Elymus innovatus* dominant, site mesic	C17
4b.	*Shepherdia canadensis* not dominant, *Equisetum* spp. dominant herbs, site hygric to subhygric	C28
5a.	Dominant tree *Larix lyallii*, occasionally codominant with *Abies lasiocarpa* (some stands may have open canopy)	C23
5b.	Dominant tree *Pseudotsuga menziesii* (if codominant with *Picea glauca* see C5)	C1
5c.	Dominant tree *Picea mariana*, *Pinus contorta* may be codominant	C8
5d.	Dominant trees *Picea engelmannii* and *Pinus albicaulis*	C12
5e.	Dominant tree *Pinus contorta*, *Picea* spp. may be codominant	6
5f.	Dominant tree *Picea* spp., *Abies lasiocarpa* may be codominant	11
6a.	Dominant shrub *Menziesia glabella*	C20
6b.	Dominant shrub *Alnus crispa*	C10
6c.	Dominant shrub *Salix glauca*	C36
6d.	Dominant shrub *Ledum groenlandicum*	C29
6e.	Dominant shrub *Juniperus communis*	C3
6f.	Dominant shrub *Shepherdia canadensis*	7
6g.	Shrub layer sparse, may have well developed dwarf shrub layer	9
7a.	*Aster conspicuus* 10–20%, site mesic	C6
7b.	*Aster conspicuus* <10%, site various	8
8a.	Dominant dwarf shrub *Vaccinium scoparium*	C18
8b.	Dominant dwarf shrub *Linnaea borealis*	C19
9a.	Herb-dwarf shrub layer sparse, bryoid layer well developed with *Hylocomium splendens* and *Pleurozium schreberi* dominant, site mesic	C11
9b.	Herb-dwarf shrub layer moderate to dense, sites mesic or subxeric	10
10a.	*Vaccinium caespitosum* dominant dwarf shrub, *Cladonia* spp. <25%, site mesic to subxeric	C9
10b.	*Empetrum nigrum* dominant dwarf shrub, *Cladonia* spp. >25%, site subxeric	C35
10c.	*Juniperus communis* and *Arctostaphylos uva-ursi* dominant dwarf shrubs, site subxeric	C3
11a.	Herb-dwarf shrub layer dominated by *Equisetum* spp.	12
11b.	Herb-dwarf shrub layer not dominated by *Equisetum* spp.	13
12a.	Shrub layer dense, dominated by *Rosa acicularis*, *Arnica cordifolia*, *Elymus innovatus* and *Mertensia paniculata* usually absent, Montane, site subhygric to hygric, *Picea* usually *Picea glauca*	C4
12b.	Shrub layer sparse, *Rosa acicularis* usually absent, *Arnica cordifolia*, *Elymus innovatus* and *Mertensia paniculata* usually present, Lower Subalpine, site mesic to subhygric, *Picea* usually *Picea engelmannii*	C32
13a.	Shrub layer dominated by *Rosa acicularis*, Jasper only	C27
13b.	Shrub layer dominated by *Menziesia glabella*	C14

13c Shrub layer dominated by *Vaccinium membranaceum* (or *Rhododendron albiflorum*) C21
13d Shrub layer dominated by *Salix vestita*, *Cassiope tetragona* present C24

13e Shrub layer dominated by *Ledum groenlandicum*, *Empetrum nigrum* usually present C30
13f Shrub layer dominated by *Shepherdia canadensis* 14
13g Shrub layer sparse 15
14a *Thuidium abietinum* dominant bryophyte C26
14b *Hylocomium splendens* dominant bryophyte C37
15a *Thuidium abietinum* dominant bryophyte, Jasper only C2
15b *Thuidium abietinum* not dominant bryophyte, both Banff and Jasper 16
16a *Vaccinium membranaceum* dominant dwarf shrub, *Barbilophozia lycopodioides* dominant bryophyte C21
16b *Vaccinium membranaceum* not dominant dwarf shrub, *Hylocomium splendens* (occasionally *Pleurozium schreberi* or *Dicranum* spp.) dominant bryophyte 17
17a Herb-dwarf shrub layer cover <15%, *Vaccinium scoparium* usually absent, Lower Subalpine C13
17b Herb-dwarf shrub layer cover >15%, *Vaccinium scoparium* usually present, Lower or Upper Subalpine 18
18a Herb-dwarf shrub layer dominated by *Phyllodoce glanduliflora* (or sometimes *Phyllodoce empetriformis*), herb cover low, Upper Subalpine C34
18b Herb-dwarf shrub layer dominated by *Elymus innovatus*, *Arnica cordifolia* and *Linnaea borealis*, herb cover high, Lower Subalpine C31
18c Herb-dwarf shrub layer dominated by *Vaccinium scoparium*, herb cover variable, Upper Subalpine C15

II KEY TO OPEN FOREST TYPES

1a Tree layer dominated by *Pinus flexilis*, often with *Pseudotsuga menziesii* O2
1b Tree layer dominated by *Pseudotsuga menziesii* O5
1c Tree layer dominated by mixture of *Picea* spp., *Abies lasiocarpa*, *Pinus albicaulis* and *Pinus contorta*; *Pseudotsuga menziesii* may be present at lower altitudes; usually on steep, colluvial, subxeric site (some open C35 may key here) O4
1d Tree layer dominated by *Betula* spp. O16
1e Tree layer dominated by *Picea glauca* and *Picea mariana* O7
1f Tree layer dominated by *Pinus contorta* with prominent *Juniperus communis* and *Arctostaphylos uva-ursi* in understory ..... open variant of C3
1g Tree layer dominated by *Picea glauca* or *Picea engelmannii*, *Abies lasiocarpa* may be codominant 2
2a *Ledum groenlandicum* dominant shrub O11
2b *Salix* spp. dominant shrub 3
2c *Potentilla fruticosa* dominant shrub O3
2d *Juniperus communis* dominant shrub O17
2e Shrub layer sparse or dominated by tree regeneration 6
3a *Salix vestita* dominant shrub 4
3b Dominant shrub *Salix* spp. other than *Salix vestita* 5
4a *Arctostaphylos rubra* dominant in herb-dwarf shrub layer O12
4b *Pedicularis bracteosa* dominant in herb-dwarf shrub layer O14
5a *Elymus innovatus* dominant herb, site mesic O18
5b *Carex* spp. dominant herb, site hygric to hydric O6

6a. Herb–dwarf shrub layer dominated by *Dryas octopetala* O19
6b. Herb–dwarf shrub layer dominated by *Phyllodoce glanduliflora*, *Cassiope mertensiana* or other ericaceous dwarf shrubs O10
6c. Herb–dwarf shrub layer dominated by *Valeriana sitchensis*, *Erigeron peregrinus* or other herbs O9

III. KEY TO SHRUB VEGETATION TYPES

1a. *Abies lasiocarpa* (or occasionally *Picea engelmannii*) dominant shrub, snow avalanche path S2
1b. *Salix scouleriana* and *Alnus spp.* dominant shrubs, Jasper S6
1c. *Salix barrattiana* dominant shrub S8
1d. Various *Salix* spp., *Betula glandulosa* or *Betula pumila* dominant 2
  2a. *Scirpus caespitosus* dominant herb S3
  2b. *Kobresia myosuroides* dominant herb S9
  2c. *Danthonia intermedia* dominant herb S11
  2d. *Equisetum arvense* dominant herb S7
  2e. None of the above 3
3a. *Potentilla fruticosa* usually present 4
3b. *Potentilla fruticosa* usually absent 5
  4a. Bryoid cover dense, *Tomenthypnum nitens* present, *Arctostaphylos uva-ursi* usually hydric, level to gentle slope S1
  4b. Bryoid cover sparse, *Tomenthypnum nitens* absent, *Arctostaphylos uva-ursi* usually present, site mesic to subxeric, moderate to steep slope S10
5a. *Elymus innovatus* cover $\geq$10%, *Salix barrattiana* usually absent S12
5b. *Elymus innovatus* cover <10%, *Salix barrattiana* usually present (5–20%) S4

IV. KEY TO LOW SHRUB–HERB VEGETATION TYPES

Dominant low shrub *Potentilla fruticosa* L1
Dominant low shrubs *Juniperus communis* and *Salix glauca*, snow avalanche path L2
Dominant low shrub *Cassiope tetragona*, snowbed L4
Dominant low shrubs *Phyllodoce glanduliflora* and *Cassiope mertensiana* L5
Dominant low shrub *Juniperus horizontalis* L6
Dominant low shrub *Salix arctica* L7

V. KEY TO HERB–DWARF SHRUB VEGETATION TYPES

1a. *Dryas* spp. dominant or codominant 2
1b. *Dryas* spp. not dominant 4
  2a. *Dryas drummondii* dominant H8
  2b. *Dryas integrifolia* dominant, *Carex rupestris* codominant, Jasper only H15
  2c. *Dryas octopetala* dominant, may contain *Dryas integrifolia* but *Carex rupestris* not codominant, see v.t. description for other differences. 3
3a. *Kobresia myosuroides*, *Arctostaphylos uva-ursi* codominant H4
3b. *Salix nivalis*, *Silene acaulis* codominant H1
  4a. Elevation <1700 m, subxeric to xeric grasslands 5

	4b.	Elevation mostly >1700 m, not subxeric to xeric grasslands	8
5a.	*Agropyron* spp. dominant		6
5b.	*Agropyron* spp. not dominant		7
	6a.	*Agropyron dasystachyum* dominant, *Artemisia frigida* codominant	H7
	6b.	*Agropyron spicatum* usually dominant, *Elymus innovatus* often codominant	H19
7a.	*Koeleria cristata* dominant, *Artemisia frigida* codominant		H6
7b.	*Stipa richardsonii* dominant, *Koeleria cristata* codominant		H13
	8a.	Site subhydric to hydric, very poorly drained	9
	8b.	Site drier and better drained	10
9a.	*Eriophorum angustifolium* dominant		H10
9b.	*Carex aquatilis* or *Carex rostrata* dominant		H11
9c.	*Caltha leptosepala* and *Trollius albiflorus* codominant		H9
	10a.	Lichens dominant, sparsely vegetated, high Alpine elevations	H12
	10b.	Graminoids dominant	11
	10c.	Forbs dominant	14
11a.	*Carex* spp. dominant		12
11b.	*Elymus innovatus* dominant		13
	12a.	*Carex nigricans* dominant, Alpine snowbed	H2
	12b.	*Carex scirpoidea* dominant, Montane–Lower Subalpine fluvial site	H3
13a.	*Fragaria virginiana, Epilobium angustifolium* abundant, site mesic		H5
13b.	*Koeleria cristata, Arctostaphylos uva-ursi* (*Hedysarum sulphurescens* in Banff) abundant, site subxeric		H14
13c.	*Saxifraga bronchialis* abundant, site xeric to subxeric		H20
	14a.	Site subxeric to xeric, *Saxifraga bronchialis* and *Elymus innovatus* dominant	H20
	14b.	Site mesic to hygric, *Saxifraga bronchialis* and *Elymus innovatus* usually absent	15
15a.	*Caltha leptosepala* and *Trollius albiflorus* dominant		H9
15b.	*Erigeron peregrinus* and *Valeriana sitchensis* dominant		H16

SIGNIFICANT SPECIES

During the Ecological Land Classification, four species of vascular plants and two species of lichens new to Alberta were collected. *Hippuris montana* Ledeb. was collected in wet Alpine areas of western Jasper and occurs otherwise in Alaska, Yukon, Northwest Territories, British Columbia and Washington. *Sedum divergens* Watson was collected on rocky, Subalpine avalanche slopes in northern Jasper and occurs also in Washington, Oregon, British Columbia, and southeastern Alaska. *Tsuga heterophylla* (Raf.) Sarg. (western hemlock) was collected in moist *Picea engelmannii–Abies lasiocarpa* Subalpine forests along the Continental Divide in northern Banff and western Jasper. It ranges from southern Alaska to California, and interior British Columbia to northwestern Montana and western Alberta. *Vaccinium ovalifolium* J. E. Smith (oval-leaved blueberry) was collected in moist Lower Subalpine *Picea engelmannii–Abies lasiocarpa* forests in northern Banff and in northern and western Jasper. This wide ranging species also occurs in Alaska, Washington, Oregon, Idaho and western Montana as well as eastern North America and eastern Asia. The lichen *Caloplaca epithallina* Lynge was collected in dry Upper Subalpine grassland in both Banff and Jasper and occurs otherwise in New Mexico, Colorado, South Dakota, and Greenland. The other lichen, *Thelidium decipiens* (Nyl.) Kremp. was collected in the Alpine of Banff and is circumpolar, arctic–alpine in range. These six species all have small populations in the parks and are rare as defined below.

A list of rare species both vascular and nonvascular, was compiled. A rare vascular species is considered to occur within a restricted geographical area, usually <500 km², and at usually <10 collection sites. Also, the plant is often at the edge of its

geographical range. All three criteria generally indicate a small population in the parks. In addition, a list of nearly rare plants and those with a range boundary in the parks was also compiled. The list of 152 rare vascular species and 28 nearly rare or range boundary species is in Volume II of this report along with information on occurrence in the parks. A list of 57 rare liverworts and mosses, and 30 rare lichens is also contained in Volume II. Further information on these species is in Volume II of this report. Due to a more limited knowledge of the ranges and abundances of nonvascular as compared to vascular plants, a slightly different definition of "rare" was used. The status "rare" was based on an abundance scale (dominant, common, infrequent, uncommon, rare) reflecting the quantity of the species in the parks as assessed by botanists familiar with the bryophytes and lichens of the Rocky Mountains.

WILDLIFE

The most spectacular, observable wildlife of Banff and Jasper National Parks are the eight species of ungulates. They occur in the parks primarily because of the availability of suitable habitat and the protection provided by the National Parks Act. Steep terrain and flat valley bottoms provide a variety of grasslands, shrub meadows and forests which, combined with moderate snow fall and areas of low snow accumulation, allow these species to forage in the winter. Much of the vegetated portion of the parks is used only in summer by elk, mule deer and white-tailed deer because winter snow accumulations are too deep for efficient travel and foraging. Part of the populations of these species is able to survive the winter within the parks, while the remainder winter outside the parks. Most sheep, goats, moose and caribou are resident in the parks year-round. Bison occurred in the mountains historically and recently one bull has survived in the lower Athabasca Valley in Jasper since 1978.

The number and variety of ungulates and other prey sustain a wide variety of carnivores. Wolves and coyotes are relatively common in Jasper. In Banff, wolves are relatively rare and most packs range east of the park, while coyotes are relatively common. Red foxes occur in both parks but are rare. Cougars are very rare, with most sightings near the townsites. Lynx are widespread but uncommon. There is a great variety of *Mustelidae*, the weasel family, in both parks. Martens and ermines are common in all forested areas. Fishers are rare and only occur in forests along the Continental Divide. Long-tailed weasels, least weasels and mink are uncommon throughout both parks. The present status of otters is not fully known but they are generally rare. Badgers have a spotty distribution in Banff.

Black bears and grizzly bears occur throughout both parks. Grizzlies are more common in the Front Ranges than the Main Ranges. Black bears have not been studied but appear to be more abundant in the Main Ranges and at lower elevations.

In addition, there are 34 other species of mammals that occur or have occurred in the two parks. There are four species of shrews; the water and pigmy shrews are rare. Seven species of bats have been recorded in in the parks. All are rare or uncommon but the big-brown and little-brown bats are the most common. Three species of lagomorphs have been recorded. Pikas and varying hares are relatively common and there is one specimen record of white-tailed jack rabbit. The remaining twenty species of mammals belong to the order *Rodentia*. The most common are deer mouse, Gapper's red-backed vole, red squirrel and Columbian ground squirrel. The Northern pocket gopher is suspected to occur only at the Ghost Lakes in Banff while the Richardson's water vole is rare but patchily distributed in both parks. Northern flying squirrels are present and widespread but their abundance is not known. Muskrats are restricted to low elevation ponds but beavers periodically invade valleys up to treeline.

Banff and Jasper National Parks support a wide variety of birds particularly during spring and summer. The great elevational range (1050 to 3350 m) and the varied terrain results in a diversity of habitats that contribute to the variety of birdlife. Also,

species characteristic of both eastern and western Canada come into contact along the Rocky Mountains. So far, 281 species have been recorded in both parks.

Alpine species, such as white-tailed and willow ptarmigan, grey-crowned rosy finch, golden-crowned sparrow, water pipit and horned lark occur in most high elevation meadows. A few species of waterfowl breed at lower elevations. Many others migrate through the mountains in small to moderate numbers. Most notable among the raptors are the breeding population of golden eagles and the small autumn migration of prairie and peregrine falcons. Migrating shorebirds occur in small numbers on lakes at all elevations. Twelve species of owls have been recorded in the two parks but only eight appear to have bred here. Black swifts nest at Maligne and Johnston Canyons, the only known breeding sites in Alberta. Most species of warblers and vireos occur at low elevations while sparrows are distributed into the Alpine. Dippers inhabit most streams and in winter some are concentrated on the Bow River below Banff townsite. The seven species of corvids are among the most obvious of the parks' avifauna.

Amphibians and reptiles are less common than birds. Of the six species only the western toad is widespread. Wood frogs and spotted frogs breed in Montane and Subalpine ponds while the long-toed salamander is restricted to some Montane ponds. The boreal chorus frog occurs in the lowest portion of the Montane in the Athabasca Valley. Wandering garter snakes are rare even at the lowest elevations. The warm springs at the Cave and Basin in Banff provide the only known snake hibernaculum.

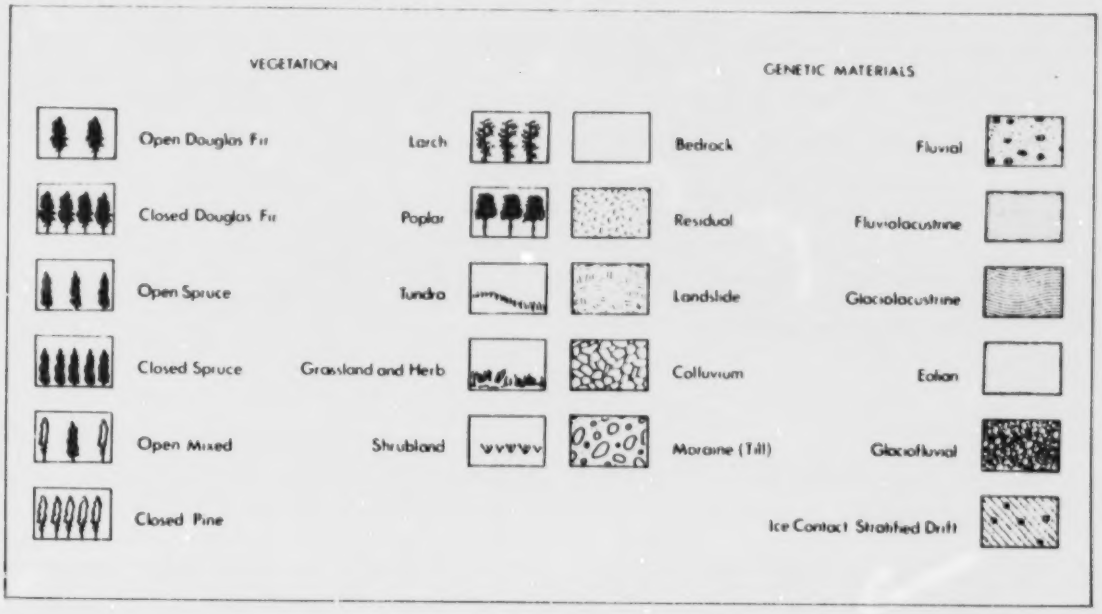
Further details on all species of wildlife are in the species accounts in Volume III and the bird checklist.

CHAPTER III - SUMMARY ECOSECTION/ECOSITE DESCRIPTIONS

ECOSYSTEM/ECOSITE DESCRIPTIONS.....B.D. Walker, W.S. Taylor, D.T. Allan, I.G.W. Corns and W.D. Holland
WILDLIFE.....G.L. Holroyd and K.J. Van Tighem

The Ecosite descriptions in this section are abbreviated from the information given for soils and vegetation in Volume II, and wildlife in Volume III. They summarize the main features of these resources and are arranged alphabetically by the two letter abbreviation. Fig. 7 is a legend of the symbols used in the landscape schematics.

Fig 7. Legend of symbols used in Ecosite landscape schematics.



The interpretive comments in the Management Considerations section use a common or dominant element selected from the entire ecological concept of an Ecosection. For example, the effect of coarse texture is highlighted for glaciofluvial deposits such as AT or BV and the effect of poor drainage is emphasized in Ecosections like CV. Yet, the comments do not represent just one of the resource disciplines. Thus, the interpretive guidelines used in Waterton Lakes National Park or Yoho National Park may result in limitations for soils that are different than the evaluation used in Banff-Jasper where a more holistic ecological concept was adopted.

AL - ALTRUDE ECOSECTION

The Altrude (AL) Ecosection encompasses calcareous fluvial fan and apron landforms dominated by Brunisolic soils and lodgepole pine or Engelmann spruce-subalpine fir forests within the Lower Subalpine portion of the Subalpine Ecoregion. AL occurs primarily on lower slopes and floors of valleys. Two AL Ecosites are separated by vegetational differences as outlined in Table 17.

Table 17. General features of the AL Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
AL1	Fan & apron	Fluvial material B (calcareous, coarse-stratified)	Eutric Brunisol	Lodgepole pine forest (C19)
AL2	Fan & apron	Fluvial material B (calcareous, coarse-stratified)	Eutric Brunisol	Engelmann spruce - subalpine fir forest (C13,C31).

AL surfaces are often channeled. Slopes range from 2 to 45%. Orthic and Cumulic Regosols occur in narrow strips along present and recently abandoned stream channels. Soils are well to moderately well drained.

WILDLIFE

Table 18. Wildlife features of the AL Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
AL1	high	deer elk	high	wolverine lynx wolf cougar coyote	medium	snowshoe hare columbian ground squirrel golden-mantled ground squirrel western jumping mouse	medium
AL2	low	moose	high	coyote	medium	red squirrel red-backed vole porcupine	high

AL is moderately to highly important to wildlife. AL1 includes highly important habitat for some ungulates and carnivores while AL2 is highly important for coyotes. A large number of small mammal species occur in the AL Ecosection but only in moderate numbers. While both Ecosites receive moderate snowfall, AL1 is warmer because of more southerly exposure.

MANAGEMENT CONSIDERATIONS

AL tracts with gentle slopes generally have no landform, soil, or vegetational characteristics limiting campground, trail, or related uses. Locally occurring coarse textures and high water tables may present problems for sewage disposal; on the other hand, the coarse textured material provides gravel for construction.

Most of the AL tracts have streams that provide suitable domestic water supplies.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

AT - ATHABASCA ECOSECTION

The Athabasca (AT) Ecosection encompasses terraced landforms of calcareous glaciofluvial material in the Montane Ecoregion. It is dominated by Brunisolic soils and either lodgepole pine forest or a pattern of dry grassland > lodgepole pine forest. Two Ecosites are separated on the basis of vegetational differences as outlined in Table 19. Representative landscape positions are shown in Figs. 24 and 27.

Table 19. General features of the AT Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
AT1	Terraced	Glaciofluvial material B (calcareous, coarse textured)	Eutric Brunisol	Lodgepole pine forest (C3, C6, C19)
AT3	Terraced	Glaciofluvial material B (calcareous, coarse textured)	Eutric Brunisol	Dry grassland (H6) > lodgepole pine forest (C3)

AT1 and AT3 occur on broad valley floors. The terraced surfaces are often channeled. Slopes range from 1 to 15%. A thin veneer of Eolian material B (altered, medium textured) occurs commonly in southern Banff and sporadically in southwestern Jasper; a thin veneer of Eolian material A (calcareous, medium textured) occurs from Jasper townsite eastward in the Athabasca River valley and near Saskatchewan Crossing in Banff. Soils are rapidly to well drained; many AT3 soils have a thin, surficial deposit of calcareous eolian material.

WILDLIFE

AT is very important to wildlife especially ungulates, carnivores and bats. Some small mammals also occur in large numbers. The relatively warm temperature and low snow

Table 20. Wildlife features of the AT Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
AT1	very high	elk deer	very high	cougar wolf coyote lynx	medium	bat snowshoe hare red squirrel deer mice	medium
AT3	very high	deer elk	high	weasel coyote wolf cougar	high	deer mouse	high

accumulation contribute to the suitability for wildlife. Critical ungulate habitat occurs on these Ecosites particularly when there are interspersed grasslands.

MANAGEMENT CONSIDERATIONS

Level topography and valley floor positions within the warm, dry Montane Ecoregion are conducive to many uses. The coarse textures provide extensive and readily available gravel and sand supplies. Because of ineffective ion filtration, AT should be tested before use for sewage disposal. Such coarse textures allow easy passage of water and thus, the soils are droughty, causing slow vegetation growth and problems in revegetation. In addition, AT is of limited areal extent and its unforested segments attract many uses.

AZ - AZURE ECOSECTION

The Azure (AZ) Ecosection has a dry > wet landscape pattern on hummocky and ridged landforms consisting of noncalcareous, coarse textured, ice contact stratified drift in the Upper Subalpine portion of the Subalpine Ecoregion. Dystric Brunisols and Engelmann spruce - subalpine fir open forest characterize dry (rapidly to well drained) upland segments. Wet (imperfectly to poorly drained) depressional segments are dominated by Gleysolic and Organic soils under wet shrub thicket and wet herb meadow vegetation. General features of the AZ1 Ecosite are outlined in Table 21. Its landscape position is shown in Fig. 8.

AZ1 occurs on lower slopes and floors of a few broad valleys. Slopes range from 5 to 45%. The strongly eluviated soils have thick Ae horizons, thick sola, and weakly cemented B horizons (duric tendency).

WILDLIFE

This Upper Subalpine Ecosite is moderately important to wildlife in summer. Deep snow restricts animal activity in winter.

Fig. 8. Landscape schematic of the Azure (AZ1) and Topaz (TZ1) Ecosites in relation to other Ecosites.

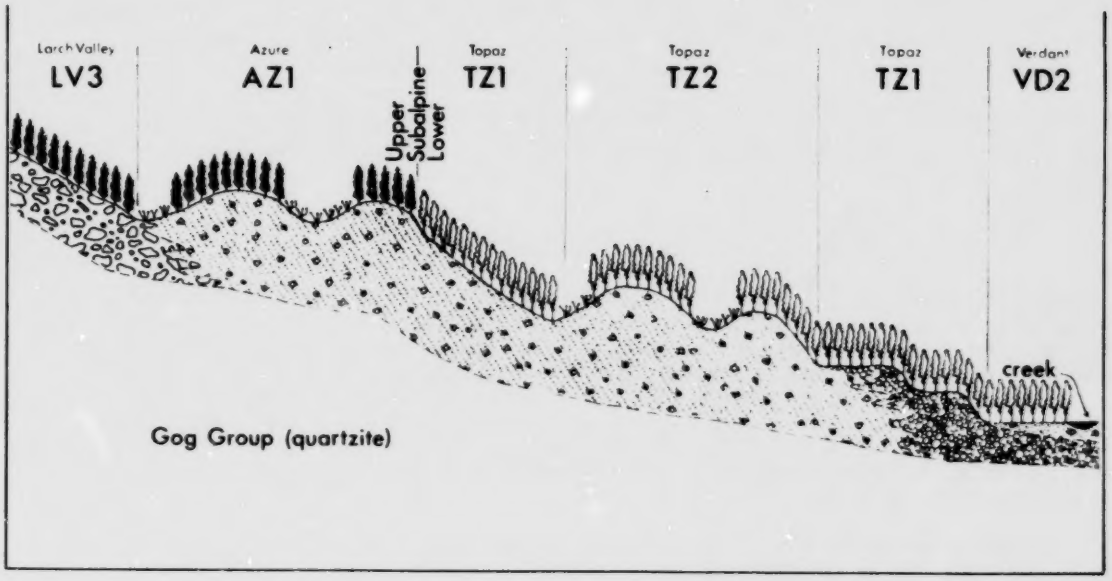


Table 21. General features of the AZ1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
AZ1	Hummocky & ridged	Ice contact stratified Drift A (noncalcareous, coarse textured)	Dry 70: Dystric Brunisol Wet 30: Gleysol > Mesisol	Engelmann spruce-subalpine fir open forest (O10) Wet shrub thicket (S8), wet herb meadow (H9)

MANAGEMENT CONSIDERATIONS

AZ1 is of limited areal extent. The coarse textured material provides gravel and sand for construction, but may present problems if used for sewage disposal because such coarse textured materials are ineffective ion filters. The dry > wet landscape pattern necessitates special considerations in trail locations and campsite construction. The

Table 22. Wildlife features of the AZ1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
AZ1	medium	caribou deer	low	cougar	low	heather vole yellow pine chipmunk	high

coarse textures are also expected to contribute to slow vegetation growth and regeneration.

BK - BAKER CREEK ECOSECTION

The Baker Creek (BK) Ecosection encompasses a dry > wet landscape pattern on ridged and hummocky landforms of calcareous glacial material in the Lower Subalpine portion of the Subalpine Ecoregion. Dry (well drained,) upland segments are dominated by an Eutric Brunisol > Gray Luvisol soil complex and lodgepole pine or Engelmann spruce – subalpine fir forests. Wet (poorly to very poorly drained) depressional segments are dominated by Gleysolic and Organic soils under wet spruce open forest, wet shrubby meadow, and birch fen. Three BK Ecosites are differentiated by genetic material and vegetational differences as outlined in Table 23. Relative landscape positions are shown in Fig. 9.

Slopes commonly range from 5 to 45%. Surficial veneers of Eolian material B (altered, medium textured) occur extensively in western Banff and southwestern Jasper, sporadically elsewhere. BK Ecosites usually occur on the benchland of broad river valley floors.

WILDLIFE

BK is highly important to wildlife. Although deep snow limits use by large mammals in winter, many species occur here in large numbers in the summer. All BK Ecosites are important to moose year–round. The mosaic of wet and dry habitats contributes to the importance of this Ecosection to wildlife.

MANAGEMENT CONSIDERATIONS

Dry portions of BK1 generally have no landform, soil or vegetational limitations for campgrounds, trails or related uses. However, the characteristic dry > wet landscape pattern necessitates special considerations in trail location and construction. BK4 and BK6 have locally occurring coarse textured materials that provide gravel sources but, conversely, may present problems in sewage disposal because of ineffectiveness in ion filtration.

BP - BOULDER PASS ECOSECTION

The Boulder Pass (BP) Ecosection encompasses hummocky landslide landforms in the Upper Subalpine portion of the Subalpine Ecoregion. Brunisolic and Regosolic soils dominate along with mixed coniferous open forest, Engelmann spruce–subalpine fir open and closed forest, and subalpine larch – subalpine fir forest. Two BP Ecosites are differentiated by soil and vegetation characteristics as outlined in Table 25.

Table 23. General features of the BK Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
BK1	Hummocky & ridged including bedrock control(blanket)	Till C (calcareous, medium textured)	Dry 70: Eutric Brunisol > Gray Luvisol	Lodgepole pine forest (C18,C19)
			Wet 30: Gleysol, Mesisol	Wet spruce open forest (O11), wet shrubby meadow(S1), birch fen (S3)
BK4	Hummocky & ridged including bedrock control (blanket)	Ice contact stratified Drift B (calcareous, variably textured)	Dry 70: Eutric Brunisol > Gray Luvisol	Lodgepole pine forest (C18, C19)
			Wet 30: Gleysol, Mesisol	Wet spruce open forest (O11), wet shrubby meadow (S1), birch fen (S3)
BK6	Hummocky & ridged including bedrock control (blanket)	Till C (calcareous, medium texture) & Ice contact stratified Drift B (calcareous, variably textured)	Dry 70: Eutric Brunisol	Engelmann spruce - subalpine fir forest (C13)
			Wet 30: Gleysol, Mesisol	Wet spruce open forest (O11), wet shrubby meadow (S1), birch fen (S3)

Relative landscape positions are shown in Fig. 10.

Surfaces are often stony and bouldery. Slopes are usually complex and range from 15 to 70%. Veneers of Eolian material B (altered, medium textured) are common on BP2 tracts in western Banff and southwestern Jasper. Soils are rapidly to moderately well drained. Eutric Brunisols occur on calcareous materials, Dystric Brunisols on noncalcareous materials. Occurrences of subalpine larch - subalpine fir forest (C23) are restricted to southern Banff. Unvegetated portions may constitute up to 50% of BP1 tracts.

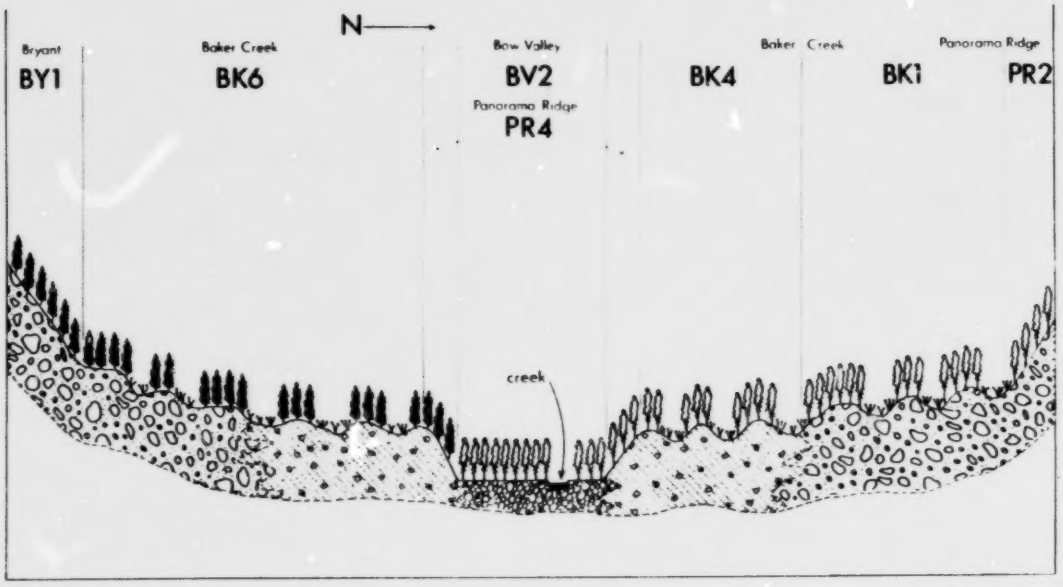
WILDLIFE

This Ecosection is of low importance to wildlife with the exception of goats. Goats forage here and probably rest in BP tracts during winter storms where BP areas occur adjacent to better foraging land. In addition, a few small mammal species occur here in high densities.

MANAGEMENT CONSIDERATIONS

BP1 has irregular topography, moderate to steep slopes, and rubbly, blocky surfaces that are limiting for campgrounds and related uses and should be considered when planning trails and roads. Vegetation is expected to recover slowly from disturbances, including fire. BP2 has limiting factors similar to those of BP1 but not as severe because fine earth materials thinly mantle the rubbly, blocky landslide deposits. As a result, the closed to open forest is thought to be more resilient to surface distrubances.

Fig. 9. Landscape schematic of the Baker Creek (BK) Ecosites in relation to other Ecosites.



BS - BOW SUMMIT ECOSECTION

The Bow Summit (BS) Ecosection encompasses inclined landforms consisting of calcareous, medium textured colluvium in the Alpine Ecoregion. It is dominated by Brunisolic and Regosolic soils and mountain avens tundra vegetation. The features of BS1 are outlined in Table 27. The landscape position of BS1 is shown in Figs. 28 and 30.

BS1 occurs on steep, usually linear slopes in areas dominated by calcareous bedrock. Slopes range from 45 to 100%. Colluvial processes are locally active and include avalanching, soil creep, cryoturbation, and solifluction. Soils are well drained. Unvegetated portions may occupy up to 50% of BS1 tracts.

WILDLIFE

This Ecosite is of low importance to most species but highly important to ungulates and some small mammals. The major attraction for ungulates is the lack of deep winter snow in these windswept areas. Rocky areas are highly important to pika and golden-mantled ground squirrels while finer soils are highly important to marmot and columbian-ground squirrel.

Table 24. Wildlife features of the BK Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
BK1	medium	moose deer elk	high	marten wolverine coyote wolf cougar	high	masked shrew red squirrels red-backed vole meadow vole western jumping mouse	high
BK4	high	elk deer moose	very high	wolf cougar coyote marten lynx	medium	snowshoe hare red-backed vole	medium
BK6	low	moose	very high	coyote marten lynx cougar	medium	snowshoe hare red-backed vole	medium

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting factors for many park uses Removal of vegetation is likely to result in wind, water, and gravitational erosion. Vegetation is expected to recover slowly from disturbances.

BV - BOW VALLEY ECOSECTION

The Bow Valley (BV) Ecosection consists of terraced landforms of calcareous glaciofluvial material and occurs in the Lower Subalpine portion of the Subalpine Ecoregion It is dominated by Brunisolic soils and either lodgepole pine or Engelmann spruce-subalpine fir forest. Three BV Ecosites are separated by vegetational differences as outlined in Table 29. Landscape positions are shown in Fig. 11.

The BV Ecosites generally occur on broad valley floors. The terraced surfaces are often channeled. Slopes range from 1 to 15%. A thin veneer of Eolian material B (altered, medium textured) is common in western Banff and southwestern Jasper. Soils are rapidly to well drained.

WILDLIFE

This Ecosection is moderately important to wildlife. Although some species occur in high numbers, this Ecosection has less wildlife than most other Montane Ecosections.

MANAGEMENT CONSIDERATIONS

Level topography and valley floor positions are conducive to many uses. The coarse textures provide extensive and readily available gravel supplies but such coarse textured material is ineffective as an ion filter, a factor to be considered when designing sewage disposal systems. Water easily passes through these materials and and

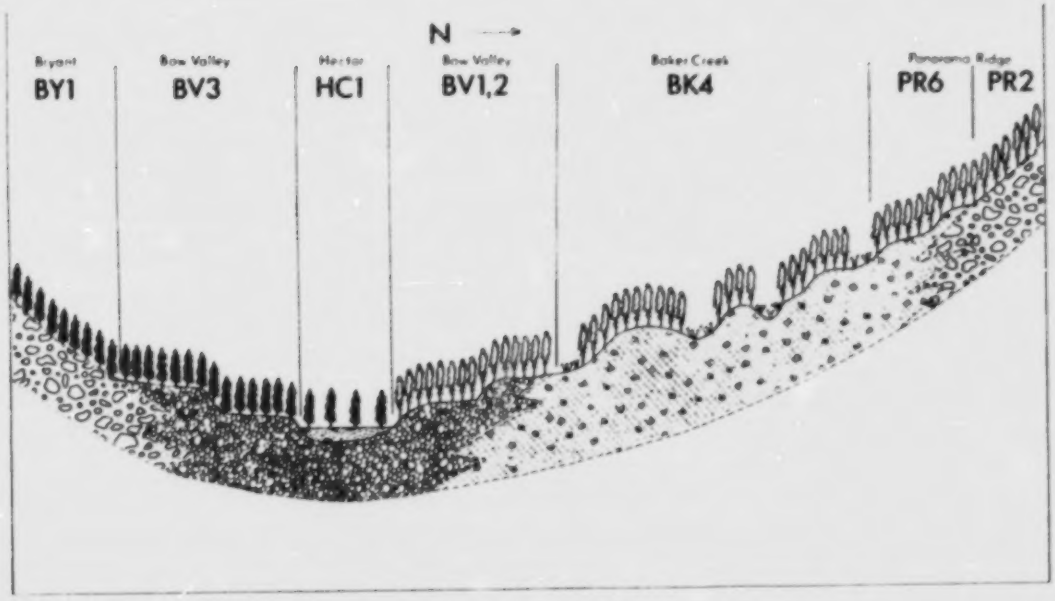
Fig 11 Landscape schematic of the Bow Valley (BV) Ecosites in relation to other Ecosites



Ecoregion. Eutric Brunisols are the dominant soils. Three BY Ecosites are

Table 30. Wildlife features of the BV Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
BV1	medium	moose	high	coyote lynx	medium	snowshoe hare red squirrel meadow vole porcupine	high
BV2	low		medium	marten	medium	red-backed vole	high
BV3	low	deer moose	low	wolf cougar	high	masked shrew red-backed vole western jumping mouse	low

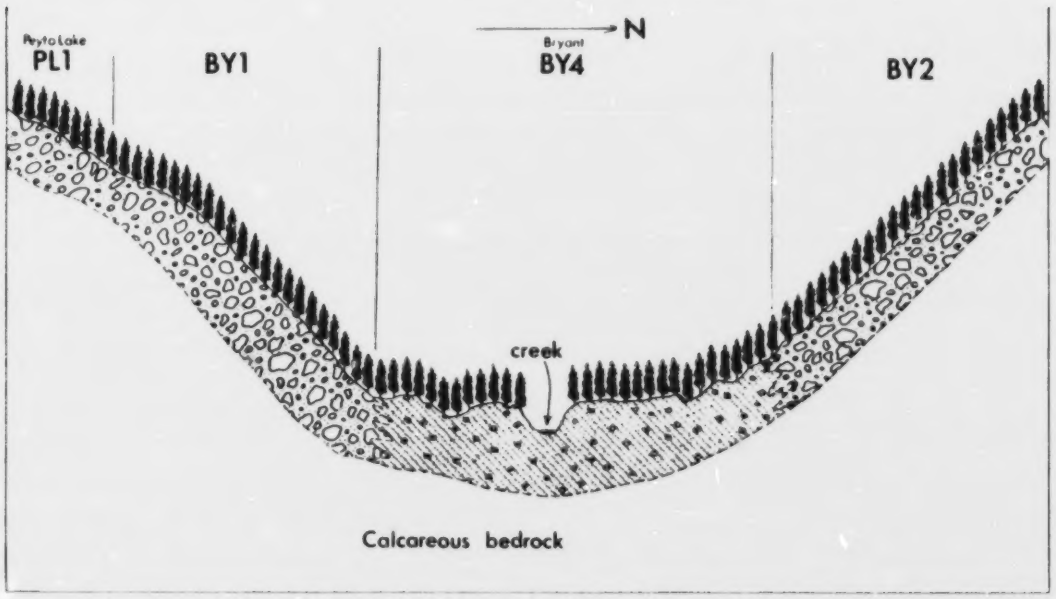
differentiated by genetic material, soil, and vegetational distinctions as outlined in Table 31. Landscape positions are shown in Fig. 12.

Table 31. General features of the BY Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
BY1	Blanket over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol > Humo-Ferric Podzol	Engelmann spruce - subalpine fir forest (C14, C21)
BY2	Blanket over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol	Engelmann spruce - subalpine fir forest (C13, C30, C31)
BY4	Blanket over inclined and hummocky bedrock, hummocky	Ice contact stratified Drift B (calcareous, variably textured)	Eutric Brunisol	Engelmann spruce - subalpine fir forest (C13, C14, C30)

BY1 occurs most often on northerly aspects in western Banff and Jasper; BY2 occurs most often in eastern Banff and Jasper. Slopes range from 15 to 70% and are often gullied on BY1 and BY2, 5 to 45% for BY4. Surficial veneers of Eolian material B (altered, medium textured) occur extensively in western Banff and Jasper and are therefore most abundant on BY1. The development of Bf, podzolic Bf, and similar horizons is related to the occurrence of Eolian material B. Soils are well to moderately well drained.

Fig. 12 Landscape schematic of the Bryant (BY) Ecosite in relation to other Ecosites.



WILDLIFE

This Ecosection is moderately important to wildlife. BY2 is highly important to caribou in Jasper. Snowshoe hare and lynx are common on BY2 and BY4. Breeding birds typical of subalpine spruce-fir forest occur in high densities in this Ecosection.

MANAGEMENT CONSIDERATIONS

Steepness of slope is a factor to consider in planning park uses. Eolian material B veneers are extensive on many BY1 tracts and tend to erode easily where vegetation is removed. Locally occurring avalanche paths and seeps may affect certain park uses on BY1 and BY2. BY4 has no characteristics limiting for campgrounds, trails or related uses. Locally occurring gravel sources on BY4 may present problems if such sites are used for sewage disposal (ineffective ion filtration).

BZ - BRAZEAU ECOSECTION

The Brazeau (BZ) Ecosection encompasses hummocky residual landforms within the Lower Subalpine portion of the Subalpine Ecoregion. It is dominated by lithic Brunisolic

Table 32. Wildlife features of the BY Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
BY1	low	moose	medium		high	red-backed vole porcupine	high
BY2	medium	caribou moose	high	lynx coyote	medium	snowshoe hare red-backed vole porcupine	low
BY4	low		high	marten lynx	low	snowshoe hare	high

soils and Engelmann spruce–subalpine fir or lodgepole pine forests. Two BZ Ecosites are separated by vegetational differences as outlined in Table 33.

Table 33. General features of the BZ Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
BZ 1	Hummocky	Residuum A (noncalcareous medium textured) and Residuum B (calcareous, medium textured)	Eutric and Dystric Brunisol (lithic phases)	Engelmann spruce - subalpine fir forest (C30, C31)
BZ 2	Hummocky	Residuum A (noncalcareous, medium textured) and Residuum B (calcareous, medium textured)	Eutric and Dystric Brunisol (lithic phases)	Lodgepole pine forest (C18, C29)

The landforms usually consist of failed Mesozoic shale bedrock that now occupies valley floor and lower slope positions. Slopes range from 5 to 15% on BZ1 and 15 to 45% on BZ2. Soils are well drained. Dystric Brunisols are associated with Residuum A; Eutric Brunisols with Residuum B. BZ occurs only in Jasper.

WILDLIFE

BZ is moderately important to wildlife but highly important to small mammals, moose and deer. Red-backed vole occurs in high densities here.

Table 34. Wildlife features of the BZ Ecosites

Ecosite	Ungulates		Carnivores		Small Mammals		Birds
	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
BZ1	medium	moose deer	medium	weasel	high	deer mouse red-backed vole	low
BZ2	medium	moose deer	low	marten	high	red-backed vole	medium

MANAGEMENT CONSIDERATIONS

BZ1 and BZ2 are of very limited areal extent. Shallow soils and bedrock are the major factors to consider in planning of park uses.

CA - CAVELL ECOSECTION

The Cavell (CA) Ecosection encompasses morainal landforms consisting of noncalcareous, medium textured till within the Lower Subalpine portion of the Subalpine Ecoregion. It is dominated by Dystric Brunisols and Engelmann spruce-subalpine fir or lodgepole pine forests. Three CA Ecosites are separated by a dry > wet landscape pattern and vegetational differences as outlined in Table 35. Landscape positions are shown in Fig. 13.

The dry > wet CA1 frequently includes failed slopes and occurs on valley floors including benchlands and on lower valley wall slopes. A few CA1 tracts are dominated by Till A (noncalcareous, coarse textured), a few others by a medium textured variant of Ice Contact Stratified Drift A (noncalcareous, coarse textured). Slopes range from 5 to 45%. Dry segments have well to moderately well drained soils; wet segments have poorly to very poorly drained soils.

Slopes for CA2 and CA4 range from 15 to 70%; soils of these two Ecosites are well to moderately well drained.

Surficial veneers of Eolian material B (altered, medium textured) occur extensively on CA1 and CA2 in western Banff and southwestern Jasper, sporadically on CA4. Occasional occurrences of Humo-Ferric Podzols are associated with the eolian veneers.

WILDLIFE

This Ecosection is moderately important to wildlife. It is highly important to some carnivores and small mammals. Deep winter snow restricts large mammal activity.

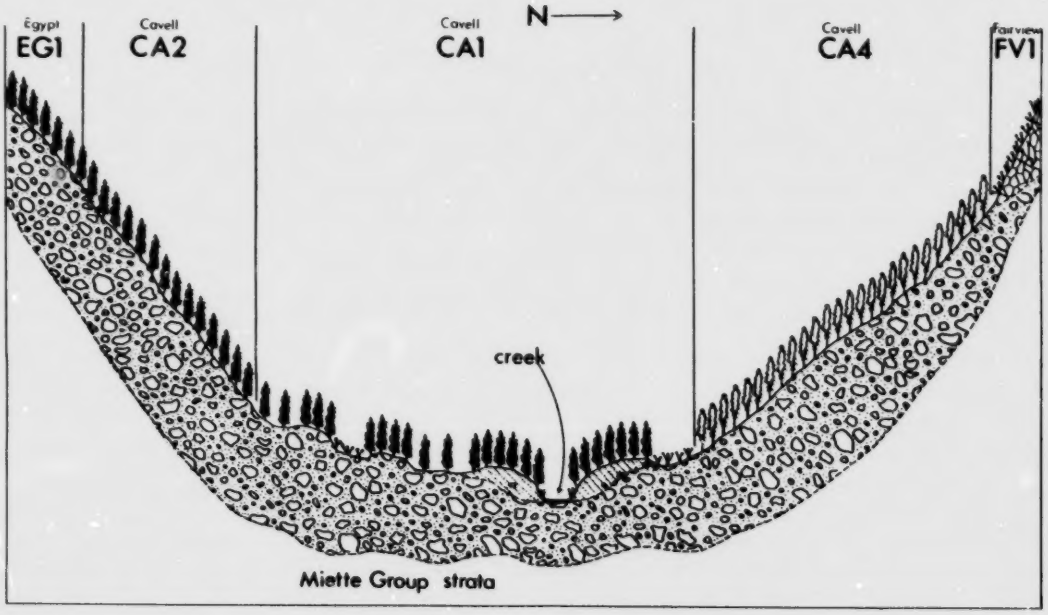
MANAGEMENT CONSIDERATIONS

Dry portions of CA1 have no characteristics limiting for campgrounds, trails, or related park uses. The characteristic dry > wet landscape requires special considerations in trail location and construction. Removal of surface and subsurface materials may

Table 35. General features of the CA Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
CA1	Hummocky & ridged including bedrock control (blanket)	Till B (noncalcareous, medium textured)	Dry 70: Dystric Brunisol Wet 30: Gleysol, gleyed Podzolic, Mesisol	Engelmann spruce - subalpine fir forest (C14, C13, C21) Wet spruce open forest (O11), wet Engelmann spruce-subalpine fir open forest (O14), wet shrubby meadow (S1), birch fen (S3).
CA2	Blanket over inclined bedrock	Till B (noncalcareous, medium textured)	Dystric Brunisol	Engelmann spruce - subalpine fir forest (C14, C13, C21).
CA4	Blanket over inclined bedrock	Till B (noncalcareous, medium textured)	Dystric Brunisol	Lodgepole pine forest (C19, C20).

Fig. 13 Landscape schematic of the Cavell (CA) Ecosites in relation to other Ecosites.



create seepage-induced slope failure. Steepness of slope is the major factor to consider in planning park uses for CA2 and CA4. Also, avalanche paths and seeps will affect certain uses locally.

Table 36. Wildlife features of the CA Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
CA1	medium		high	marten weasel lynx	medium	masked shrew snowshoe hare red-backed vole	high
CA2	low		high	marten lynx	medium	snowshoe hare red-backed vole	medium
CA4	medium	moose	medium	marten	medium	deer mice red-backed vole	low

CN - CYCLONE ECOSECTION

The Cyclone (CN) Ecosection encompasses fluvial fan and apron landforms dominated by Regosolic soils and dry to moist shrub thicket vegetation in the Upper Subalpine portion of the Subalpine Ecoregion. It occurs on valley floors and lower slopes mainly within the Front Ranges. The features of the CN1 Ecosite are outlined in Table 37. Landscape position is shown in Fig. 30.

Table 37. General features of the CN1 Ecosite.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
CN1	Fan, apron	Fluvial materials A & B (noncalcareous & calcareous, coarse-stratified)	Regosol, Humic Regosol	Dry shrub thicket (S10), moist shrub thicket (S12)

Fluvial blankets, terraces, and level floodplains occur in minor amounts. Modification by snow avalanching and channeling is common. Slopes range from 5 to 45%. Soils are well to moderately well drained although some tracts contain small wet sites.

WILDLIFE

Table 38. Wildlife features of the CN1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
CN1	high	elk	low	coyote cougar	high	columbian ground squirrel deer mouse heather vole meadow vole long-tailed vole	low

This shrubby Ecosection is highly important to all wildlife, particularly small mammals and, in summer and autumn, elk.

MANAGEMENT CONSIDERATIONS

Regosolic soils dominate, therefore flooding is sufficiently frequent to maintain these weakly developed soils. Frequency and magnitude of depositional processes are major factors to consider in planning park uses. Locally occurring coarse textures and high water tables present problems for sewage disposal. Coarse textured materials provide gravel supplies. Many tracts are avalanched.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

CP - COPPER ECOSECTION

The Copper (CP) Ecosection encompasses residual landforms in the Upper Subalpine portion of the Subalpine Ecoregion. It is dominated by lithic Dystric Brunisols and Engelmann spruce–subalpine fir open and closed forests and subalpine larch–subalpine fir forest. The features of the CP1 Ecosite are outlined in Table 39. Landscape position is shown in Fig. 14.

CP1 occurs primarily on valley shoulders and spurs; some tracts occur on failed bedrock. The parent material is weathered from either Miette Group bedrock in the Main Ranges or noncalcareous Mesozic strata in the Front Ranges. Surficial veneers of Eolian material B (altered, medium textured) occur extensively in western Banff, sporadically elsewhere. Limited occurrences of Humo–Ferric Podzols are associated with the eolian veneers. Slopes range from 15 to 60%. Soils are well to moderately well drained. Occurrences of subalpine larch–subalpine fir forest (C23) are restricted to southern Banff.

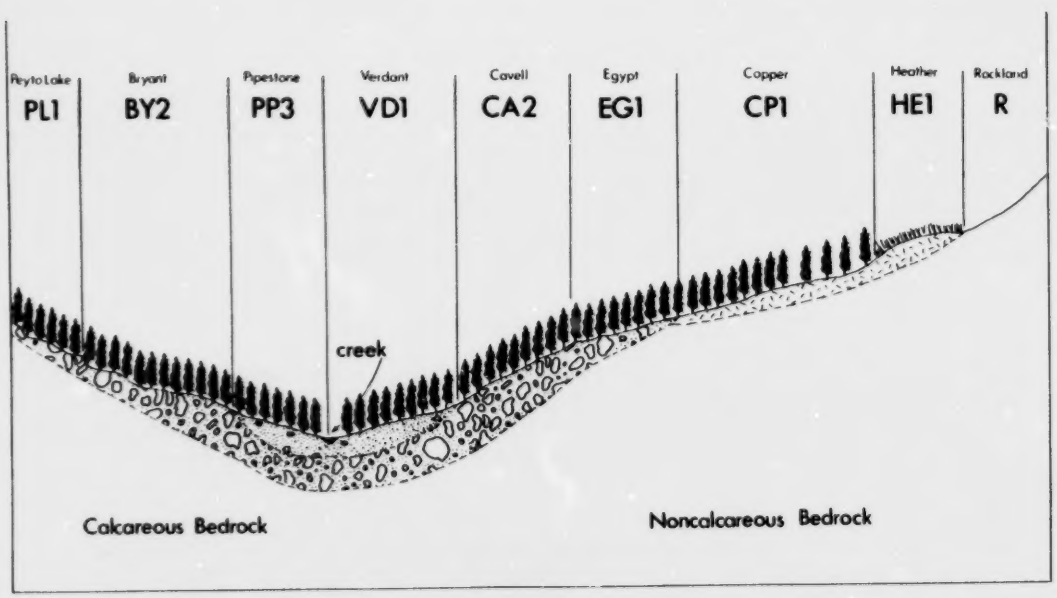
WILDLIFE

This rocky Ecosection is moderately important to wildlife, although few species occur here in large numbers.

Table 39. General features of the CP1 Ecosite.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
CP1	Inclined, hummocky, & ridged	Residuum A (noncalcareous, medium textured)	Dystric Brunisol (lithic phases)	Engelmann spruce - subalpine fir closed & open forest (C15, O10), subalpine larch - subalpine fir forest (C23)

Fig. 14 Landscape schematic of the Copper (CP1) Ecosite in relation to other Ecosites.



MANAGEMENT CONSIDERATIONS

CP1 is of limited areal extent. Shallow soils and bedrock are the major factors to consider when planning park uses.

Table 40. Wildlife features of the CP1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
CP1	medium	bighorn sheep caribou	medium	weasel	low	heather vole	medium

CV - CONSOLATION VALLEY ECOSECTION

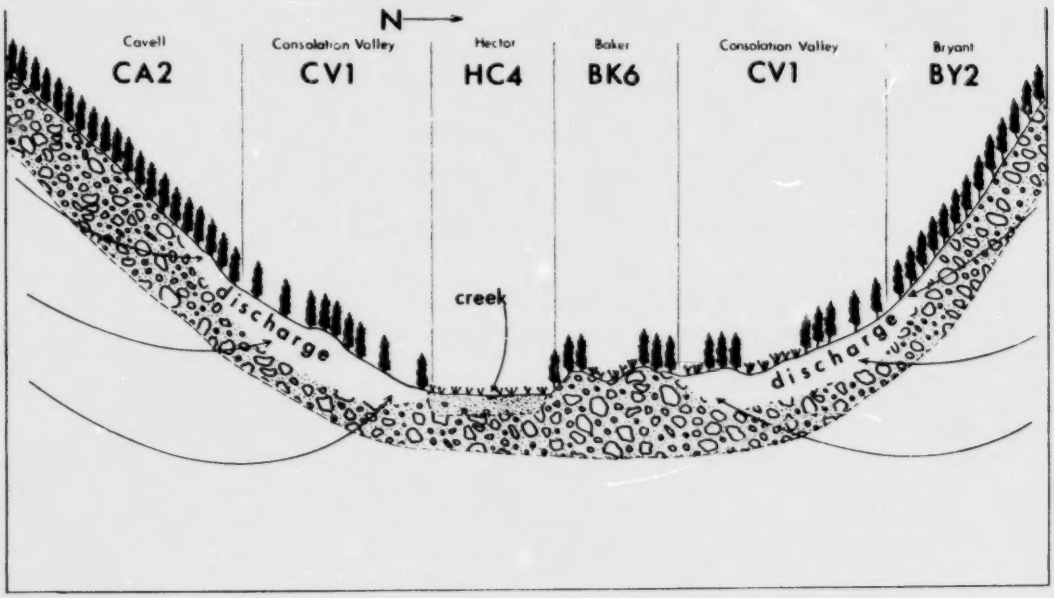
The Consolation Valley (CV) Ecosection encompasses a wet > dry landscape pattern on glacial landforms in the Lower Subalpine portion of the Subalpine Ecoregion. Wet (poorly to very poorly drained) segments are dominated by Gleysolic, gleyed Podzolic, and Organic soils under wet Engelmann spruce–subalpine fir open forest, wet spruce open forest, wet shrubby meadow, and birch fen vegetation. Dry (well to moderately well drained) segments are dominated by Brunisolic soils occurring under Engelmann spruce–subalpine fir or lodgepole pine forests. Features of the CV1 Ecosite are outlined in Table 41. Landscape position is shown in Fig. 15.

Table 41. General features of the CV1 Ecosite.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
CV1	Inclined, hummocky, & ridged including bedrock control (blanket) > sloping fen	Till B (noncalcareous, medium textured) & low lime phase of Till C (calcareous, medium textured) > fen peat	Wet 80: Gleysol, gleyed Podzolic, Mesisol Dry 20: Eutric & Dystric Brunisol	Wet spruce open forest (O11), wet Engelmann spruce - subalpine fir open forest (O14) > wet shrubby meadow (S1), birch fen (S3). Engelmann spruce - subalpine fir forest (C13), lodgepole pine forest (C20, C29)

CV1 tracts occur in groundwater discharge areas, often on valley floors and lower valley wall slopes; seepage is characteristic. Other genetic materials that dominate a few CV1 tracts include Till A (noncalcareous, coarse textured), Ice Contact Stratified Drift B (calcareous, variably textured), and Ice Contact Stratified Drift A (noncalcareous, coarse textured). Postglacial slope failure is a common feature of CV1 landforms. Slopes commonly range from 5 to 45%. Surficial veneers of Eolian material B (altered, medium textured) and Fluviolacustrine material A (altered, fine-stratified) occur extensively in western Banff and southwestern Jasper.

Fig. 15 Landscape schematic of the Consolation Valley (CV1) Ecosite in relation to other Ecosites.



WILDLIFE

Table 42. Wildlife features of the CV1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
CV1	medium	moose	very high	coyote marten weasel wolverine	high	yellow pine chipmunk meadow vole porcupine	high

CV1 is highly important to wildlife. Although moose is the only ungulate to make much use of this Ecosite, many species of other mammals and birds occur here in large numbers.

MANAGEMENT CONSIDERATIONS

Poor to very poor drainage resulting from seepage and groundwater discharge limits most land uses unless expensive construction techniques are followed. Of particular consideration is the hydrologic importance of CV in maintaining and regulating stream flow.

Evidence of postglacial slope failure suggests that this may recur.

DV - DEVONA ECOSECTION

The Devona (DV) Ecosection encompasses ridged (dune) landforms of calcareous eolian material in the Montane Ecoregion in Jasper, in particular along the Athabasca River valley floor downstream from Jasper Lake. Regosolic soils are associated with white spruce forest or shrubby grassland. Two DV Ecosites are separated by vegetational differences (Table 43). Landscape position is shown in Fig. 16.

Table 43. General features of the DV Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
DV1	Ridged	Eolian material A (calcareous, medium textured).	Regosol	Shrubby grassland (L6).
DV2	Ridged	Eolian material A (calcareous, medium textured).	Regosol	White spruce forest (C27).

The eolian material is actively aggrading, particularly on DV1. Unvegetated blowouts are associated with active wind erosion. Slopes range from 5 to 30%. White spruce thickets occupy moist depressions between ridges on DV1. Soils are rapidly to well drained and extremely calcareous. Cumulic Regosols in the DV2 Ecosite indicate periods of geomorphic inactivity interspersed with periods of eolian deposition.

WILDLIFE

DV is very important to wildlife. In winter, it is critical range for deer and elk. Consequently, large carnivores are also concentrated adjacent to these grasslands. Some breeding birds occur here in high densities.

Fig 16 Landscape schematic of the Devona 1 (DV1) Ecosite in relation to other Ecosites.

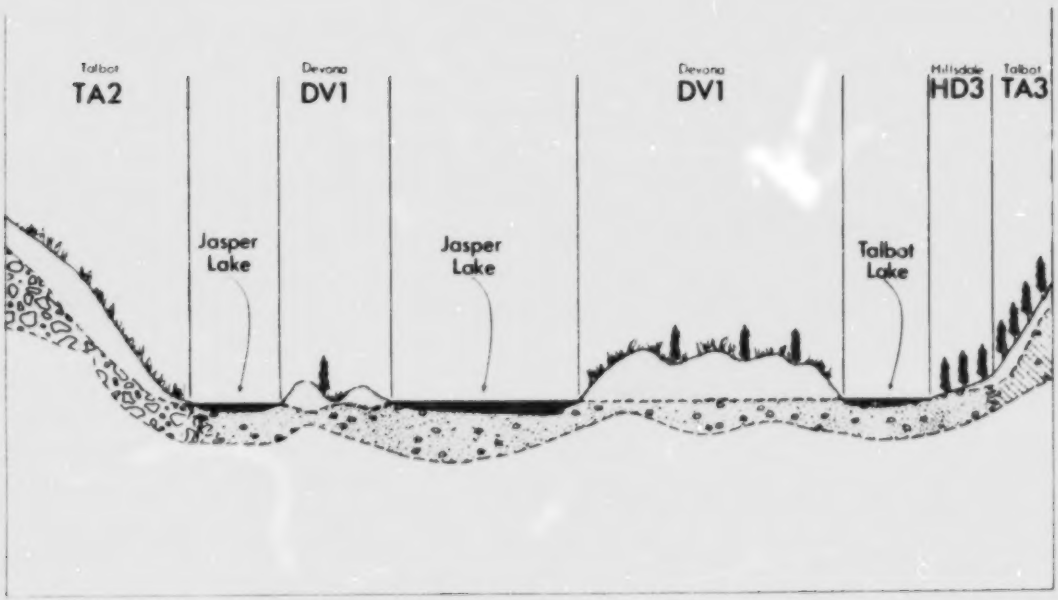


Table 44. Wildlife features of the DV Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
DV1	very high	elk deer	high	wolf weasel coyote lynx	medium	deer mouse	medium
DV2	very high	elk deer	high	wolf coyote cougar	high	deer mouse	high

DV1 and DV2 are of limited areal extent. Regosolic soils dominate and indicate current and recent eolian deposition. Removal of vegetation is likely to result in wind erosion. With disturbance, vegetation is easily removed and slow to recover. However, vegetation of DV2 is more resilient than that of DV1.

EF - EIFFEL ECOSECTION

The Eiffel (EF) Ecosection encompasses morainal landforms comprised of noncalcareous, coarse textured till within the Alpine Ecoregion. Dystric and Sombric Brunisols and Podzols characterize the soils. The vegetation is dominantly heath tundra. General features of the EF1 Ecosite are outlined in Table 45 and landscape position is shown in Fig. 21.

Table 45. General features of the EF1 Ecosite.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
EF1	Blanket & veneer over inclined, hummocky and ridged bedrock	Till A (noncalcareous, coarse textured)	Dystric & Sombric Brunisol, Ferro-Humic Podzol	Heath tundra (L5)

EF1 occurs in the Main Ranges and is associated primarily with Gog Group strata. Surficial veneers of Eolian material B (altered, medium textured) occur on EF1 tracts in western Banff and southwestern Jasper. Podzolic soils are associated with these veneers. Slopes range from 5 to 45%. Soils are well drained. Lithic soil phases occur.

WILDLIFE

Table 46. Wildlife features of the EF1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
EF1	low	caribou mountain goat	low		medium	dusky shrew hoary marmot columbian ground squirrel golden-mantled ground squirrel heather vole	low

EF1 is of low importance to wildlife.

MANAGEMENT CONSIDERATIONS

Heath tundra vegetation is slow to recover from disturbances. Stony surfaces in some localities will affect trail and campsite construction.

EG - EGYPT ECOSECTION

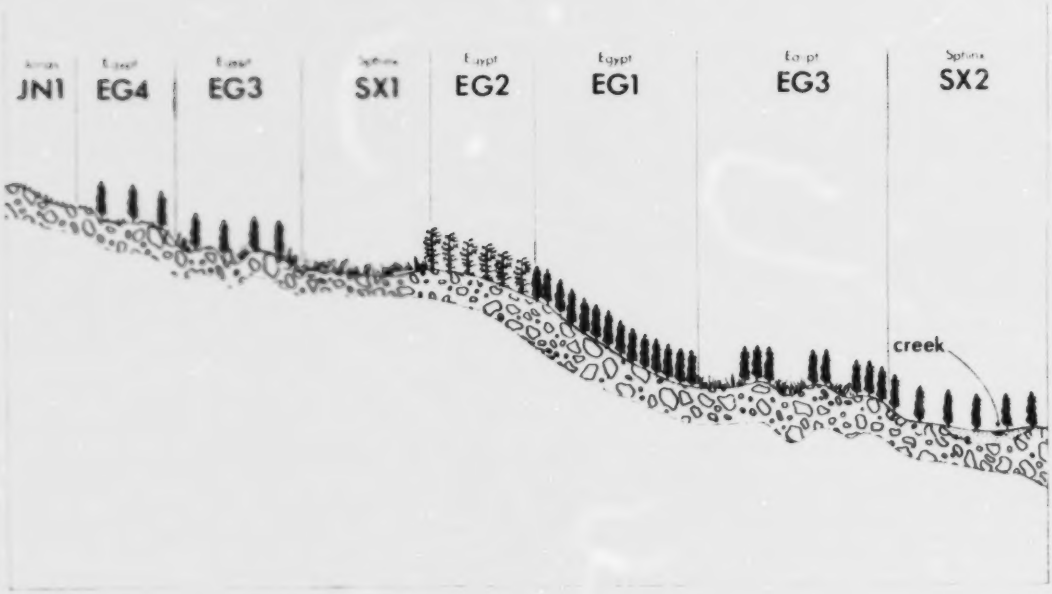
The Egypt (EG) Ecosection encompasses morainal landforms comprised of noncalcareous, medium textured till within the Upper Subalpine portion of the Subalpine Ecoregion. Dystric Brunisols are the dominant soils and occur under Engelmann spruce-subalpine fir closed and open forest, subalpine larch-subalpine fir forest, and a pattern of heath tundra plus coniferous open forest. The four EG Ecosites outlined in Table 47 are seperated by vegetational differences and a dry > wet landscape pattern. Landscape positions are shown on Fig. 17.

Table 47. General features of the EG Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
EG1	Blanket over inclined bedrock	Till B (noncalcareous, medium textured)	Dystric Brunisol	Engelmann spruce-subalpine fir closed & open forest (C15, C21, O10).
EG2	Blanket over inclined, hummocky, & ridged bedrock	Till B (noncalcareous, medium textured)	Dystric Brunisol > Humo-Ferric Podzol	Subalpine larch - subalpine fir forest (C23)
EG3	Blanket & veneer over hummocky & ridged bedrock	Till B (noncalcareous, medium textured)	Dry 70: Dystric Brunisol	Engelmann spruce - subalpine fir closed & open forest (C15,O10), subalpine larch-subalpine fir forest (C23)
			Wet 30: Gleysol, gleyed Podzolic, gleyed Brunisolic	Engelmann spruce - subalpine fir open forest (09), moist herb meadow (H16)
EG4	Blanket & veneer over inclined, hummocky & ridged bedrock	Till B (noncalcareous, medium textured)	Dystric Brunisol > Sombric Brunisol, Ferro-Humic Podzol	Heath tundra (L5) > Engelmann spruce - subalpine fir open forest (O10)

EG occurs in association with Miette Group strata in the Main Ranges, and with noncalcareous Mesozoic strata in the Front Ranges. Surficial veneers of Eolian material B

Fig 17 Landscape schematic of the Egypt (EG) Ecosites in relation to other Ecosites.



(altered, medium textured) occur extensively in western Banff and southwestern Jasper. The subdominant and accessory Podzolic soils are associated with these veneers. Slopes range from 15 to 70% for EG1 and EG4, and from 5 to 45% for EG2 and EG3. Soils are well to moderately well drained except for the wet depressional segments of EG3 which are imperfectly to poorly drained. Occurrences of subalpine larch-subalpine fir forest are restricted to southern Banff.

A few EG3 tracts occur on landforms dominated by Till A (noncalcareous, coarse textured). Depressional segments of some EG3 tracts consist of Fluvial material A (noncalcareous, coarse-stratified). Lithic soil phases are important on EG3 and EG4; turbic soil phases on EG4.

WILDLIFE

EG is moderately important to wildlife. The mosaic of habitats often supports a wide variety of small mammal species, but the deep snow precludes much use by ungulates and carnivores in winter.

Table 48. Wildlife features of the EG Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
EG1	medium	moose elk	high	coyote	medium	muskrat snowshoe hare golden-mantled ground squirrel red-backed vole porcupine	low
EG2	high	elk moose	high	marten	medium	heather vole	low
EG3	low	moose	medium	marten	medium	northern bog lemming	medium
EG4	low	caribou	low		low	heather vole	medium

MANAGEMENT CONSIDERATIONS

On EG1, steepness of slope is a major factor to consider in planning park uses. Locally occurring avalanche paths and, less often, seeps will affect certain uses. EG2 is similar to EG1 in its management concerns but is of limited areal extent. Eolian material B veneers are common on EG2 and tend to erode easily where vegetation is removed. Dry portions of EG3 have no limitations other than those mentioned above. However, the dry > wet landscape pattern requires special consideration in location and design when planning some uses, e.g. trail construction. EG4 is similar to EG1 in its management concerns but its heath tundra vegetation is slow to recover from disturbances.

EN - ENDLESS CHAIN

The Endless Chain (EN) Ecosection encompasses inclined landforms of noncalcareous, coarse textured colluvium in the Upper Subalpine portion of the Subalpine Ecoregion. It is dominated by Dystric Brunisols occurring under Engelmann spruce–subalpine fir closed and open forest, mixed coniferous open forest, and an avalanche complex of v.t.s. Vegetational differences are the main criteria separating the three EN Ecosites (Table 49). Landscape positions are shown in Fig. 18.

EN occurs primarily in the Main Ranges on or below steep, rocky, valley walls in areas dominated by Gog Group strata. Surficial veneers of Eolian material B (altered, medium textured) occur sporadically. Slopes commonly range from 45 to 100%. Soils are rapidly to well drained. Avalanche paths characteristically occupy more than 50% of EN2. Unvegetated portions may constitute up to 50% of EN2 and EN3 tracts. EN3 is the steepest of three EN Ecosites and has the greatest abundance of lithic soils and rock outcrops. Avalanche Complex 2, for EN2, is a heterogeneous complex of v.t.s. that includes subalpine fir–willow (S2), willow–dwarf birch–shrubby cinquefoil (S10), juniper–willow (L2), hairy wild rye – wild strawberry –fireweed (H5), fleabane–valerian (H16), plus intergrades, with S2 being most abundant.

Table 49. General features of the EN Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
EN1	Blanket & veneer over inclined bedrock	Collovium A (noncalcareous, coarse textured)	Dystric Brunisol	Engelmann spruce - subalpine fir closed & open forest (C15, C21, O10)
EN2	Blanket & veneer over inclined bedrock, apron	Colluvium A (noncalcareous, coarse textured)	Dystric Brunisol > Regosol	Avalanche Complex 2 > mixed coniferous open forest (O4) > Engelmann spruce subalpine fir open forest (O10)
EN3	Blanket & veneer over inclined bedrock > inclined bedrock	Colluvium A (noncalcareous, coarse textured)	Dystric Brunisol > Regosol	Mixed coniferous open forest (O4) > Engelmann spruce - subalpine fir open forest (O10)

Fig. 18 Landscape schematic of the Endless Chain Ecosites in relation to other Ecosites.

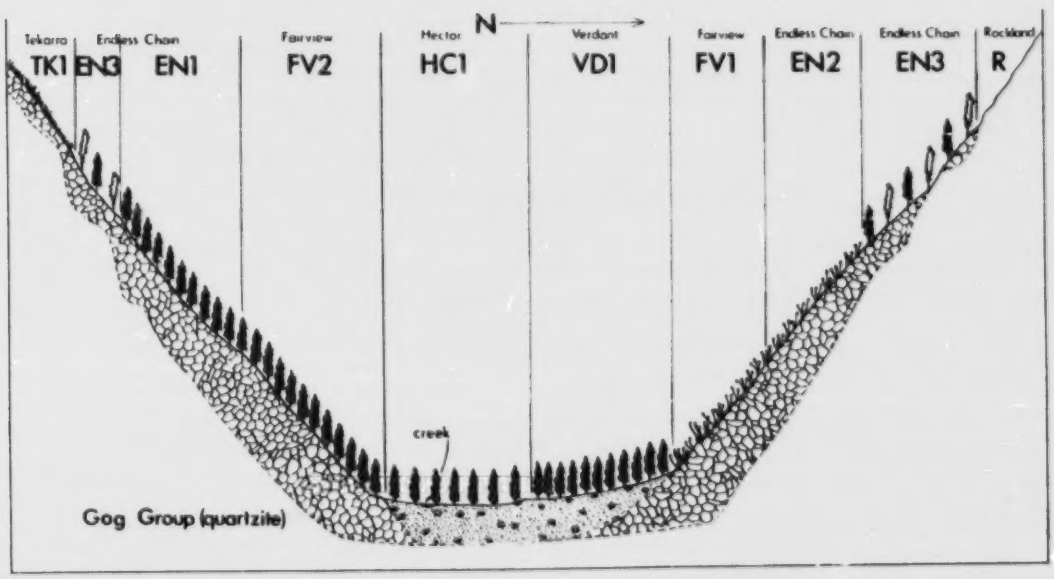


Table 50. Wildlife features of the EN Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
EN1	medium	mountain goat	low		medium		low
EN2	medium	mountain goat	low		medium	meadow vole western jumping mouse	low
EN3	medium	deer elk	low	wolf coyote	low	snowshoe hare	low

This steep Ecosection is of low importance to wildlife, although EN1 and EN2 are highly important to goats.

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting factors to be considered for many park uses. Stony surfaces, shallow soils, and bedrock outcrops affect planning for uses such as trails, especially on EN3. Snow avalanching, whether local (on EN1, EN3) or extensive (EN2), will affect winter uses. EN1 is of limited areal extent. Vegetation on EN3 is expected to recover slowly from disturbances.

FR - FIRESIDE ECOSECTION

The Fireside (FR) Ecosection (Table 51) consists of fluvial landforms dominated by Brunisolic soils and lodgepole pine forest within the Montane Ecoregion. The FR Ecosection occurs primarily on lower slopes and floors of valleys.

Table 51. General features of the FR1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
FR1	Fan & apron	Fluvial material B, (calcareous, coarse-stratified)	Eutric Brunisol	Lodgepole pine forest (C6, C19)

FR1 includes landforms comprised of Fluvial material A (noncalcareous, coarse-stratified) in the Miette River valley in Jasper. Surfaces are often channeled. Slopes range from 2 to 30%. Soils are well drained. Regosolic soils occur in narrow strips along present and recently abandoned stream channels. Lodgepole pine/dwarf

bilberry (C9) is common on FR1 tracts located in southern Banff.

WILDLIFE

Table 52. Wildlife features of the FR1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
FR1	high	deer elk moose	high	coyote wolf cougar lynx	high	snowshoe hare red squirrel beaver deer mice red-backed vole heather vole	high

FR1 is highly important to wildlife. Many species occur here in large numbers. Ungulates are most abundant in winter. The lush ground cover also supports many species of small mammals and breeding birds.

MANAGEMENT CONSIDERATIONS

FR1 tracts with gentle slopes generally have no characteristics limiting uses for campgrounds, trails, or other related park uses. Locally occurring coarse textures and high water tables may present problems for sewage disposal. Coarse textured materials provide gravel for construction purposes.

EACH TRACT SHOULD BE EVALUATED FOR SPECIFIC PROPOSED USES.

FV - FAIRVIEW ECOSECTION

The Fairview (FV) Ecosection encompasses inclined landforms composed of noncalcareous, colluvial materials in the Lower Subalpine portion of the Subalpine Ecoregion. It is dominated by Dystric Brunisols occurring under Engelmann spruce–subalpine fir forest and an avalanche complex of v.t.s. Table 53 outlines two FV Ecosites separated by vegetational differences. Landscape positions are shown in Fig. 18.

FV occurs primarily in the Main Ranges on or below steep valley walls and is associated with noncalcareous bedrock. Surface veneers of Eolian material B (altered, medium textured) occur sporadically. Slopes commonly range from 45 to 90%. Soils are rapidly to moderately well drained. Snow avalanch paths characteristically occupy more than 50% of FV1. Unvegetated portions may constitute up to 50% of FV1 tracts. Avalanche Complex 1, for FV 1, is a heterogeneous complex of v.t.s. that includes subalpine fir–willow (S2), willow–dwarf birch–shrubby cinquefoil (SI0), hairy wild rye – wild strawberry – fireweed (H5), aspen / hairy wild rye – showy aster (C22), plus intergrades, with S2 being most abundant.

Table 53. General features of the FV Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
FV1	Blanket & veneer over inclined bedrock, apron	Colluvium A (noncalcareous, coarse textured + Colluvium B (noncalcareous, medium textured)	Dystric Brunisol > Regosol	Avalanche Complex 1 > Engelmann spruce - subalpine fir forest (C13, C14)
FV2	Blanket over inclined bedrock, apron	Colluvium A (noncalcareous, coarse textured) + Colluvium B (noncalcareous, medium textured)	Dystric Brunisol	Engelmann spruce-subalpine fir forest (C13, C14, C21)

WILDLIFE

Table 54. Wildlife features of the FV Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
FV1	low		medium	weasel wolverine	medium	masked shrew pika golden-mantled ground squirrel western jumping mouse	high
FV2	medium		low		medium	red-backed vole	medium

FV is moderately important to wildlife, especially small mammals and birds.

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting factors to be considered for many park uses. Stony surfaces will affect planning for uses such as trails. Snow avalanching, whether local (on FV2) or extensive (FV1), will affect winter uses.

GA - GARONNE ECOSECTION

The Garonne (GA) Ecosection encompasses hummocky landslide deposits in the Montane Ecoregion. It is dominated by Brunisolic and Regosolic soils and lodgepole pine forest. The general features of the GA1 Ecosite are outlined in Table 55.

Table 55. General features of the GA1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
GA1	Hummocky	Landlside material (calcareous, medium textured)	Eutric Brunisol, Regosol	Lodgepole pine forest (C3, C6, C19)

Surficial veneers of Eolian material A (calcareous, medium textured) overlie the landslide material in Jasper and veneers of Eolian material B (altered, medium textured) overlie landslide material in Banff. Complex slopes range from 15 to 45%. Soils are rapidly to well drained. Rubbly, blocky surfaces occur locally.

WILDLIFE

Table 56. Wildlife features of the GA1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
GA1	high	deer elk	high	wolf coyote cougar	medium		high

GA is highly important to wildlife. The varied topography, vegetation and low elevation contribute to its importance to many species of ungulates, carnivores and birds.

MANAGEMENT CONSIDERATIONS

GA1 is of very limited areal extent. Irregular topography, often with moderate to steep slopes, and sites with rubbly, blocky surfaces are limiting for park uses such as campgrounds and may affect the design of trails and roads.

GT - GOAT ECOSECTION

The Goat (GT) Ecosection encompasses calcareous, morainal landforms dominated by a Brunisolic > Regosolic soil pattern within the Lower Subalpine portion of the Subalpine Ecoregion. Vegetation is characterized by lodgepole pine forest, white spruce open forest, mixed coniferous open forest, dry grassland, and low shrub-herb meadow. Table 57 outlines two GT Ecosites differentiated by patterns of soils and vegetation. Landscape positions are shown in Figs. 19 and 29.

Table 57. General features of the GT Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
GT1	Blanket over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol > Regosol	Lodgepole pine forest (C3), mixed coniferous open forest (O4), white spruce open forest (O17)
GT2	Blanket over inclined & ridged bedrock, inclined	Till C (calcareous, medium textured)	Northerly: Eutric Brunisol Southerly: Eutric Brunisol, Humic Regosol	Lodgepole pine forest (C6, C19) Dry grassland (H14), low shrub-herb meadow (L1)

GT1 occurs on valley walls primarily with southerly aspects. Soil and vegetation patterns reflect surface erosional processes including gullying, sheet erosion, and soil creep. Slopes range from 45 to 70%. Soils are rapidly to well drained. GT2 occurs in the Front Ranges, usually in association with Mesozoic strata. Surface expression reflects stream incisions on valley floors and bedrock control on valley walls and benchlands. Some GT2 tracts on river banks include Ice Contact Stratified Drift B (calcareous, variably textured). Slopes range from 30 to 90%. GT2 soils and vegetation are distributed in a pattern governed by aspect, steepness of slope, exposure, and erosional processes. Stable positions of the landscape, collectively labelled "northerly aspect" segments, are dominated by well drained Brunisolic soils under lodgepole pine forest. Eroding or recently eroded portions of the landscape, collectively labelled "southerly aspect" segments, have rapidly drained Brunisolic and Regosolic soils under grassland and shrub-herb meadow vegetation.

WILDLIFE

GT is very important to wildlife except birds. Dry, southerly, exposed slopes with grasslands are important foraging areas for ungulates and small mammals. Carnivores are attracted here by the abundant prey.

Fig. 19 Landscape schematic of the Goat Ecosites in relation to other Ecosites.

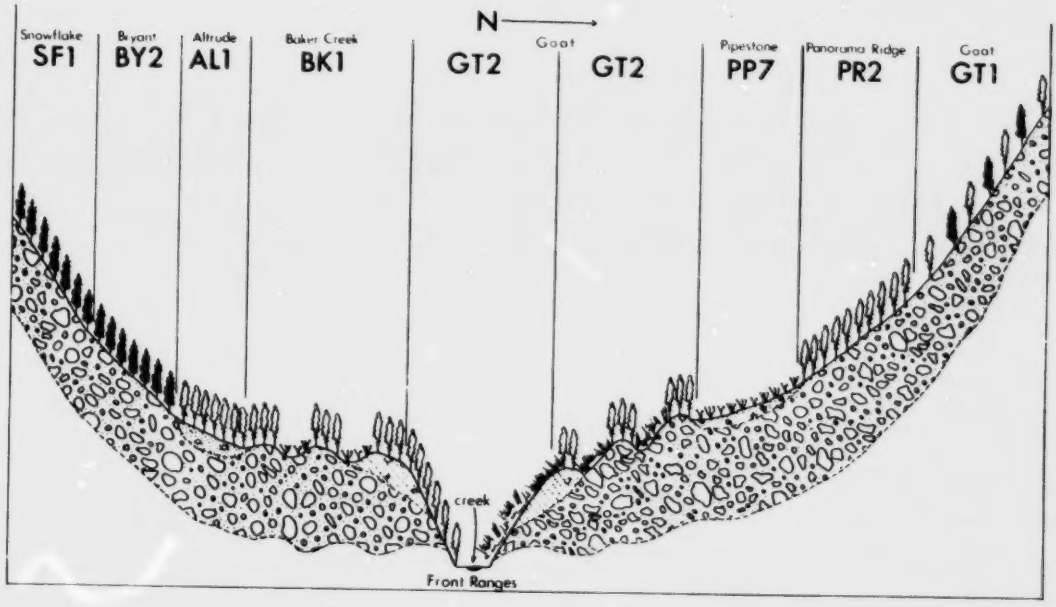

Table 58. Wildlife features of the GT Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
GT1	high	elk bighorn sheep mountain goat deer	very high	cougar wolf coyote	medium	masked shrew heather vole	low
GT2	very high	elk deer mountain goat	very high	wolf coyote cougar lynx	very high	snowshoe hare least chipmunk columbian ground squirrel deer mice northern bog lemming meadow vole	medium

MANAGEMENT CONSIDERATIONS

Steep and locally eroding slopes are limiting factors to be considered for many park uses of GT1 and GT2. On GT2 tracts, moderately sloping, forested portions are not limiting for trails and related park uses, but removal of vegetation on nonforested portions would increase erosion significantly. Nonforest vegetation is likely to recover slowly from disturbances.

HC - HECTOR ECOSECTION

The Hector (HC) Ecosection encompasses wet fluvial and fluviolacustrine landforms on valley floors in the Lower Subalpine portion of the Subalpine Ecoregion. A complex set of genetically related Gleysolic, Gleyed Regosolic, and Organic soils occur. Various groupings of Engelmann spruce forest, Engelmann spruce - subalpine fir open forest, wet shrubby meadow, birch fen, wet shrub thicket, and sedge fen differentiate the three HC Ecosites outlined in Table 59. Landscape positions are shown in Figs. 11, 15, 18, and 29.

Table 59. General features of the HC Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
HC1	Level, apron, fan > horizontal fen	Fluvial material A & B (noncalcareous & calcareous, coarse-stratified) > fen peat	Gleysol > gleyed Regosolic, Mesisol	Moist Engelmann spruce forest (C32), wet Engelmann spruce-subalpine fir open forest (O6) > wet shrubby meadow (S1), birch fen (S3)
HC2	Level	Fluviolacustrine material B (calcareous, fine-stratified)	Gleysol	Sedge fen (H11)
HC4	Level, apron, fan > horizontal fen	Fluvial materials A & B (noncalcareous & calcareous, coarse-stratified) > fen peat	Gleysol > gleyed Regoslic, Mesisol	Wet shrubby meadow (S1), birch fen (S3), wet shrub thicket (S11), sedge fen (H11)

Wetness on HC results from high water tables, seepage, and groundwater discharge and gives imperfectly to very poorly drained soils. Fluviolacustrine deposits are important accessory materials on HC1 and HC4. Soils in active or recently active sedimentation environments lack surface peat layers, whereas soils of geomorphically inactive localities have surface organic layers and include Mesisols on horizontal fens in ponded localities. Active siltation from ponded, glacial streams characterizes most HC2 tracts, hence surface peat layers are absent and a bryoid-poor variant of the H11 v.t. is dominant. Slopes are often channeled and range from 0 to 9% on HC1 and HC4, 0 to 1% on HC2.

Table 60. Wildlife features of the HC Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
HC1	medium	moose	high	wolverine wolf coyote	medium	masked shrew dusky shrew western jumping mouse	high
HC2	low		medium	weasel	low	beavers northern bog lemming meadow vole porcupine	high
HC4	high	moose elk caribou	high	weasel cougar wolf coyote	medium		high

HC is highly important to wildlife, especially birds. Ecosites with open or no forest cover are the most important. The shrub and sedge meadows are highly important moose habitat. The willow meadows are critical winter habitat for White-tailed Ptarmigan.

MANAGEMENT CONSIDERATIONS

Imperfect to very poor drainage, resulting from high water tables and local flooding, severely limits most park uses unless expensive construction techniques are followed. On some tracts, particularly on the very poorly drained HC2 Ecosites, sediment deposition accompanies flooding. Major construction activities (e.g. roads) will change sedimentation and erosional patterns. HC2 is of limited areal extent.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

HD - HILLSDALE ECOSECTION

The Hillsdale Ecosection encompasses fluvial landforms dominated by Regosolic soils in the Montane Ecoregion. Various vegetational groupings involving aspen, white spruce, lodgepole pine, and white spruce-Douglas fir forests and grassland differentiate the four HD Ecosites outlined in Table 61.

HD occurs on lower slopes and valley floors. Channeled surfaces are common. Surficial veneers of Eolian material A (calcareous, medium textured) occur north of Jasper Lake . Tracts mapped in the Miette River valley in Jasper are comprised of Fluvial material A (noncalcareous, coarse-stratified). Slopes range from 1 to 15%. Soils are rapidly to moderately well drained; gleyed soils with imperfect drainage occur on the

Table 61 General features of the HD Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
HD1	Fan, apron	Fluvial material B (calcareous, coarse-stratified)	Regosol	Aspen forest (C16)
HD2	Fan, level, apron	Fluvial material B (calcareous, coarse-stratified)	Regosol	Spruce open forest (O3)
HD3	Fan, apron	Fluvial material B (calcareous, coarse-stratified)	Regosol	White spruce forest (C2, C26, C27), white spruce-Douglas fir forest (C5)
HD4	Fan, apron	Fluvial material B (calcareous, coarse-stratified)	Regosol	Grassland (H6) - lodgepole pine forest (C3)

toes of fans and aprons.

WILDLIFE

This Montane Ecosection is very important to wildlife. Critical range for elk and deer occurs here. High densities of small mammals, birds and some carnivores were recorded on all Ecosites. HD has low snow accumulation and palatable forage which contribute to its importance to ungulates.

MANAGEMENT CONSIDERATIONS

Fluvial deposition is sufficiently frequent to maintain the dominantly Regosolic soils and is a major factor to consider in planning of park uses. Locally occurring coarse textures and high water tables present problems for sewage disposal. The coarse textured material provides gravel for construction purposes. HD4 is of limited areal extent. It is also particularly droughty and problems in revegetation are likely to occur.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

HE - HEATHER ECOSECTION

The Heather (HE) Ecosection encompasses residual and bedrock landforms in the Alpine Ecoregion. Lithic phases of Brunisolic and Regosolic soils dominate areas where soil is present, but areas of nonsoil (surface veneers <10 cm thick over bedrock) are common. Mountain avens tundra dominates most HE tracts. Table 63 outlines the features of the two HE Ecosites differentiated by consolidated versus unconsolidated bedrock and resultant effects on soil and vegetation.

HE occurs at high elevations on cols, plateaus, rounded mountain peaks and ridges, and

Table 62 Wildlife features of the HD Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
HD1	high	elk deer	high	coyote cougar marten wolf	high	columbian ground squirrel red squirrel meadow vole	high
HD2	very high	elk deer	high	wolf coyote lynx cougar	very high	masked shrew snowshoe hare red squirrel deer mice	high
HD3	high	deer moose	high	wolf coyote cougar lynx	high	snowshoe hare least chipmunk deer mice	high
HD4	very high	elk deer bighorn sheep	high	wolf cougar	high	red squirrel deer mice	high

Table 63 General features of the HE Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
HE1	Inclined, hummocky, ridged	Residuum A & B (noncalcareous + calcareous, medium textured)	Sombric + Melanic Brunisol, Humic Regosol (lithic phases)	Mountain avens tundra (H1)
HE2	Ridged bedrock > veneer over ridged + hummocky, bedrock	Calcareous bedrock > Residuum B (calcareous, medium textured)	Nonsoil >> Melanic Brunisol, Humic Regosol (lithic phases)	Unvegetated portions > mountain avens tundra (H1)

in cirques. HE1 occurs most often on Miette strata in the Main Ranges and Mesozoic strata in the Front Ranges; HE2 usually occurs on resistant carbonate strata in the Main Ranges. Slopes range up to 45% on HE1 and from 5 to 70% on HE2. Solifluction with turbic soil phases is common on HE1. Bedrock is the dominant feature of HE2 and vegetation is more extensive than soil.

Table 64. Wildlife features of the HE Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
HE1	medium	bighorn sheep mountain goat	low	weasel	medium	pika columbian ground squirrel golden-mantled ground squirrel	low
HE2	medium	bighorn sheep mountain goat	low		low	golden-mantled ground squirrel	low

HE is of low importance to all wildlife except sheep and goat which forage here intensively.

MANAGEMENT CONSIDERATIONS

Bedrock and shallow soils are major considerations in planning park uses of the HE Ecosection. Solifluction and cryoturbation are common on some HE1 tracts. Vegetation is expected to recover slowly from disturbances. HE2 is of slightly different concern than HE1, especially since rockiness is the salient feature and excludes those uses requiring unconsolidated materials, e.g. in trail building. Vegetation on HE2 is expected to recover very slowly from disturbances. Wet sites make up only a small portion of HE2 but are lushly vegetated and conspicuous. It is expected that these small wet sites can be easily damaged.

IB - ISHBEL ECOSECTION

The Ishbel (IB) Ecosection encompasses hummocky landslide deposits in the Lower Subalpine portion of the Subalpine Ecoregion. Brunisolic and Regosolic soils are associated with lodgepole pine forest, coniferous open forest, and Engelmann spruce-subalpine fir forest. Table 65 outlines the features of three IB Ecosites that are seperated primarily by vegetational differences. Landscape position is shown in Fig. 10.

IB occurs on mid to lower valley wall positions. Surfaces are often stony and bouldery. Veneers of Eolian material B (altered, medium textured) are common on IB1 and IB3 tracts in western Banff and southwestern Jasper. Soils are rapidly to well drained; Eutric Brunisols occur on calcareous materials, Dystric Brunisols on noncalcareous materials. Unvegetated portions may constitute up to 50% of IB2 tracts.

Table 65. General features of the IB Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
IB1	Hummocky	Landslide material (calcareous + noncalcareous, variably textured)	Eutric & Dystric Brunisol	Lodgepole pine forest (C18, C19, C29)
IB2	Hummocky	Landslide material (calcareous & noncalcareous, variably textured)	Regosol, Eutric + Dystric Brunisol	Mixed coniferous open forest (O4), spruce open forest (O17)
IB3	Hummocky	Landslide material (calcareous + noncalcareous, variably textured)	Eutric & Dystric Brunisol	Engelmann spruce - subalpine fir forest (C21, C30)

WILDLIFE

Table 66. Wildlife features of the IB Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
IB1	medium		medium	wolf	high	red-backed vole	medium
IB2	low		medium	wolverine	medium	pika red squirrel	medium
IB3	low	moose	medium	lynx cougar	low	masked shrew snowshoe hare	medium

IB is moderately important to wildlife. The wildlife is typical of much of the subalpine forests.

MANAGEMENT CONSIDERATIONS

Irregular topography, often with moderate to steep slopes, and sites with rubbly, blocky surfaces are limiting for campgrounds and related uses and can affect the design of trails and roads. Vegetation on IB2 is expected to recover slowly from disturbances, including fire.

JN - JONAS ECOSECTION

The Jonas (JN) Ecosection encompasses morainal landforms consisting of noncalcareous, medium textured till in the Alpine Ecoregion. A soil pattern of Dystric and Sombric Brunisols and Podzolics occurs under heath and mountain avens tundra. Table 67 summarizes characteristics of the JN1 Ecosite. Landscape position is shown in Fig. 17.

Table 67. General features of the JN1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
JN1	Blanket & veneer over inclined, hummocky, & ridged bedrock	Till B (noncalcareous, medium textured)	Dystric & Sombric Brunisol > Ferro-Humic Podzol	Heath tundra (L5), mountain avens tundra (H1)

JN1 occurs on valley walls and shoulders and in cirque basins and cols. Veneers of Eolian material B (altered, medium textured) occur extensively in western Banff and southwestern Jasper, sporadically elsewhere. Podzolic soil occurrences are associated with these veneers. Slopes range from 5 to 45%. Soils are well to moderately well drained. Solifluction and cryoturbation are common surface modifiers. Lithic and turbic soil phases occur. Heath tundra (L5) vegetation is most abundant.

WILDLIFE

Table 68. Wildlife features of the JN1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
JN1	medium	caribou bighorn sheep mountain goat	low		low	pika hoary marmot columbian ground squirrel golden-mantled ground squirrel	low

JN1 is of low importance to wildlife except some ungulates and small mammals. Sheep and goat occur in high numbers.

MANAGEMENT CONSIDERATIONS

An intricate pattern of soils and vegetation, related to drainage conditions, necessitates detailed evaluation of individual tracts for planning of park uses. Of particular concern are imperfectly to poorly drained and soliflucted sites. Vegetation is expected to recover slowly from disturbances.

KA - KATHERINE ECOSECTION

The Katherine (KA) Ecosection (Table 69) encompasses fluvial apron and fan landforms in the Alpine Ecoregion. Regosolic and Gleysolic soils occur under dwarf shrub-herb meadow and mountain avens tundra. Landscape position is shown in Fig. 20.

Table 69. General features of the KA1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
KA1	Fan, apron	Fluvial materials A & B (noncalcareous & calcareous, coarse-stratified)	Humic Regosol, Gleysol	Dwarf shrub-herb meadow (L7), mountain avens tundra (H1)

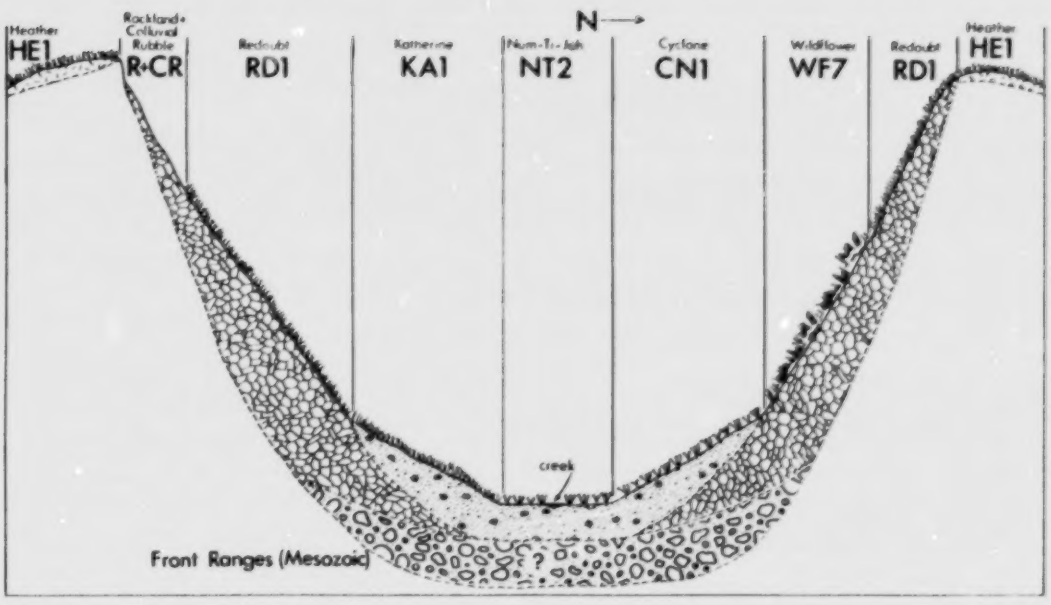
KA is most extensive in the Front Ranges and occurs on lower valley wall slopes and valley floors. Variable seepage conditions related to snow melt and soil thaw on slopes above KA maintain its moist to wet conditions (i.e. moderately well to poorly drained soils). Stratified deposits, including interbedded and mixed humus, are manifestations of episodic fluvial deposition and mixing by solifluction. Slopes range from 1 to 30% and are often channeled and soliflucted.

WILDLIFE

Table 70. Wildlife features of the KA1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
KA1	high	bighorn sheep moose elk	low		low		low

Fig. 20 Landscape schematic of the Katherine 1 (KA1) Ecosite in relation to other Ecosites.



KA1 is of low importance to wildlife overall, but highly important to sheep, moose and elk in summer. The wet alpine meadows provide summer forage for these ungulates.

MANAGEMENT CONSIDERATIONS

An intricate pattern of soils and vegetation, related to drainage and solifluction, necessitates detailed evaluation of individual tracts for trails, campgrounds, or other park uses. Of particular concern are imperfectly to poorly drained and soliflucted localities. The soils lack B horizons, suggesting that geomorphic activity or wetness are sufficiently great to maintain these weakly developed soils. Vegetation is expected to recover slowly from disturbances.

LV - LARCH VALLEY ECOSECTION

The Larch Valley (LV) Ecosection encompasses morainal landforms comprised of non-calcareous, coarse textured till in the Upper Subalpine portion of the Subalpine Ecoregion. A Brunisolic > Podzolic soil complex dominates and occurs under subalpine larch-subalpine fir forest, Engelmann spruce-subalpine fir closed and open forest, and a distinctive pattern of heath tundra plus coniferous open forest. These vegetational differences separate the three LV Ecosites (Table 71). Landscape positions are shown in Fig. 21.

Table 71. General features of the LV Ecosite

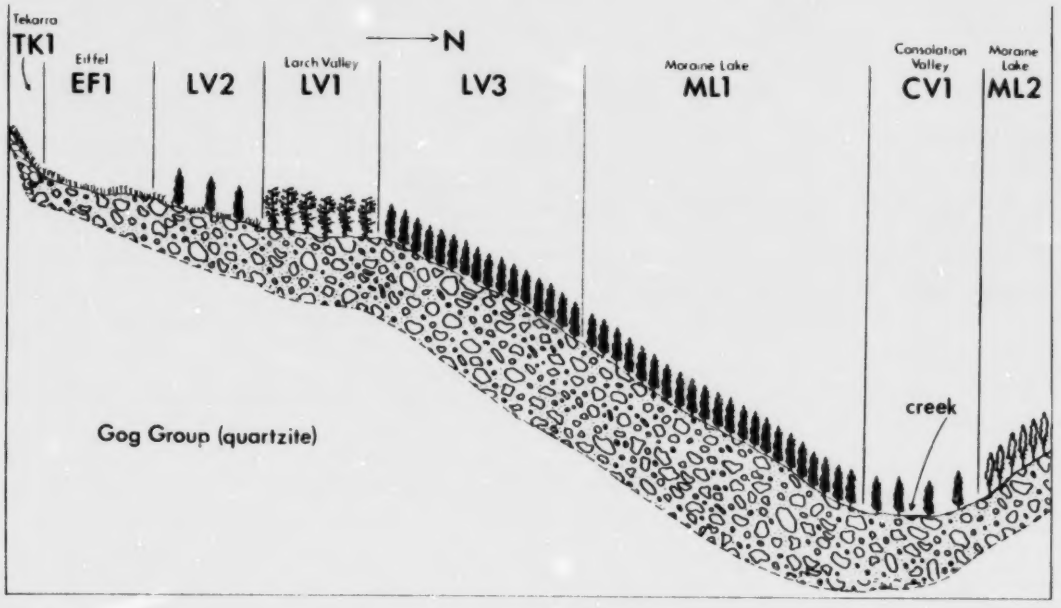
Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
LV1	Blanket over inclined, hummocky & ridged bedrock	Till A (noncalcareous, coarse textured)	Dystric Brunisol > Humo-Ferric Podzol	Subalpine larch - subalpine fir forest (C23)
LV2	Blanket, veneer over inclined, hummocky & ridged bedrock	Till A (noncalcareous, coarse textured)	Dystric Brunisol > Sombric Brunisol, Ferro-Humic Podzol	Heath tundra (L5) > Engelmann spruce - subalpine fir open forest (O10)
LV3	Blanket over inclined bedrock	Till A (noncalcareous, coarse textured)	Dystric Brunisol > Humo-Ferric Podzol	Engelmann spruce - subalpine fir closed and open forest (C15, C21, O10)

Table 72. Wildlife features of the LV Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
LV1	low	moose	low	wolf	medium	least chipmunk heather vole long-tailed vole western jumping mouse	low
LV2	low		low	weasel	medium	hoary marmots columbian ground squirrel heather vole porcupine	low
LV3	medium	mountain goat caribou	medium	marten wolverine	low	dusky shrew pika columbian ground squirrel heather vole porcupine	medium

LV occurs primarily on valley walls and shoulders, cirque basins, and cols. It occurs in the Main Ranges in areas dominated by Gog Group quartzites. Veneers of Eolian material B (altered, medium textured) occur extensively in western Banff and southwestern Jasper; the subdominant Podzolic soils are associated with these veneers. Slopes range from 15 to 70%; soils are well drained. Occurrences of subalpine larch-subalpine fir forest (C23) are restricted to southern Banff. Lithic soil phases are important on tracts mapped as LV2.

Fig. 21 Landscape schematic of the Larch Valley (LV) Ecosites in relation to other Ecosites.



WILDLIFE

LV is moderately important to wildlife, particularly small mammals which occur in high numbers here. LV3 is also important to goat and caribou in the summer.

MANAGEMENT CONSIDERATIONS

All three of the LV Ecosites have similar management concerns, except that LV1 is of limited areal extent. Steepness of slope is the major factor in planning park uses, but coarse textures may also influence certain uses. The eolian veneers, common in many areas, tend to erode easily where vegetation is removed. Locally occurring avalanche paths will affect certain uses. Heath tundra vegetation on LV2 is slow to recover from disturbances.

MC - MERLIN CASTLE ECOSECTION

The Merlin Castle (MC) Ecosection encompasses a wet > dry landscape pattern on glaciolacustrine landforms in the Lower Subalpine portion of the Subalpine Ecoregion. Wet (poorly drained) segments are dominated by Gleysolic and gleyed Brunisolic soils

under wet spruce open forest and birch fen. Dry (well to moderately well drained) segments are dominated by Luvisolic and Brunisolic soils under lodgepole pine and Engelmann spruce-subalpine fir forests. Table 73 outlines the features of the MC1 Ecosite.

MC1 occupies valley floor benchland positions. Wetness is attributed to seepage and surface water accumulation. Veneers of fen peat, Fluviolacustrine material A (altered, fine-stratified), and Eolian material B (altered, medium textured) occur locally. Slopes range from 0 to 10%.

WILDLIFE

MC1 is of low importance to wildlife.

MANAGEMENT CONSIDERATIONS

Poor drainage, resulting from surface water collection on slowly pervious, fine textured, glaciolacustrine material, severely limits most park uses unless expensive construction techniques are followed.

Table 73. General features of the MC1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
MC1	Glaciolacustrine veneer & blanket over ridged, hummocky, & undulating glacial materials	Glaciolacustrine material (calcareous, fine textured) over Ice contact stratified Drift A & B (non-calcareous, coarse textured & calcareous, variably textured)	Wet 80: Gleysol, Gleyed Eutric Brunisol Dry 20: Gray Luvisol, Eutric Brunisol	Spruce open forest (O11), birch fen (S3) Lodgepole pine forest (C29) Engelmann spruce-subalpine fir forest (C30)

Table 74. Wildlife features of the MC1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
MC1	low	moose	medium		low		low

ML - MORAINE LAKE ECOSECTION

The Moraine Lake (ML) Ecosection encompasses morainal landforms comprised of noncalcareous, coarse textured till in the Lower Subalpine portion of the Subalpine Ecoregion. Dystric Brunisols are the dominant soils. Vegetation is dominated by Engelmann spruce–subalpine fir forest, lodgepole pine forest, and Engelmann spruce–whitebark pine forest. Table 75 summarizes three ML Ecosites distinguished by vegetational differences. Landscape position is shown in Fig. 21.

Table 75. General features of the ML Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
ML1	Blanket over inclined bedrock	Till A (noncalcareous, coarse textured)	Dystric Brunisol > Humo-Ferric Podzol	Engelmann spruce - subalpine fir forest (C13, C14, C21)
ML2	Blanket over inclined bedrock	Till A (noncalcareous, coarse textured)	Dystric Brunisol	Lodgepole pine forest (C18, C20)
ML3	Blanket over inclined bedrock	Till A (noncalcareous, coarse textured)	Dystric Brunisol	Engelmann spruce - white bark pine forest (C12)

ML occurs primarily on valley walls in the Main Ranges and is associated with Gog Group quartzites. Veneers of Eolian material B (altered, medium textured) occur extensively in western Banff and southwestern Jasper, sporadically elsewhere. Podzolic soils are associated with the eolian veneers. Slopes range from 15 to 70% and are often gullied; soils are well drained. ML3 occurs only in Jasper.

WILDLIFE

ML is highly important to wildlife, especially small mammals and birds. The moist coniferous forests support a high concentration of many species of small mammals and birds.

MANAGEMENT CONSIDERATIONS

Steepness of slope is the major factor in planning park uses, but coarse textures and high coarse fragment content may also influence certain uses. Eolian material B veneers are extensive on many ML1 tracts and tend to erode easily where vegetation is removed. Locally occurring avalanche paths will affect certain uses. ML3 is of limited areal extent.

Table 76. Wildlife features of the ML Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
ML1	low	moose	medium		very high	pika least chipmunk yellow pine chipmunk golden-mantled ground squirrel red-backed vole heather vole western jumping mouse porcupine	high
ML2	low	moose	low		high	red squirrel deer mouse red-backed vole heather vole	medium
ML3	medium	deer caribou	medium	wolf marten cougar	high	yellow pine chipmunk red squirrel red-backed vole heather vole	high

MP - MOLAR PASS ECOSECTION

The Molar Pass (MP) Ecosection encompasses morainal landforms of calcareous, medium textured till in the Alpine Ecoregion. It is dominated by Brunisolic and Regosolic soils under mountain avens and heath tundra. Table 77 summarizes the MP1 Ecosite and Fig. 25 indicates the landscape position.

Table 77. General features of the MP1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
MP1	Blanket, veneer over inclined, hummocky, & ridged bedrock	Till C (calcareous, medium textured)	Eutric & Melanic Brunisol, Regosol, Humic Regosol	Mountain avens tundra (H1), heath tundra (L5).

MP1 occurs on valley walls, valley shoulders, cirque basins and cols. Veneers of Eolian material B (altered, medium textured) are most extensive on MP1 tracts of western Banff and southwestern Jasper. Slopes range from 5 to 45%. Soils are well to moderately well drained. Lithic and turbic soil phases occur. Solifluction and cryoturbation are common surface modifiers. Mountain avens tundra (H1) is abundant on most tracts.

Table 78. Wildlife features of the MP1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
MP1	medium	bighorn sheep mountain goat	low	wolverine	low	pika hoary marmot columbian ground squirrel golden-mantled ground squirrel	low

MP1 is of low importance to most wildlife. It is highly important to sheep, goat and some small mammals, especially in summer.

MANAGEMENT CONSIDERATIONS

An intricate pattern of soils and vegetation, related to geomorphic activity, necessitates detailed evaluation of individual tracts for trails, campgrounds, and related park uses. Of particular concern are soliflucted and cryoturbated localities and sites with imperfect drainage. Vegetation is expected to recover slowly from disturbances.

MQ - MOSQUITO ECOSECTION

The Mosquito (MQ) Ecosection encompasses fluvial fan and apron landforms dominated by Brunisolic and Regosolic soils and Engelmann spruce–subalpine fir open and closed forests in the Upper Subalpine portion of the Subalpine Ecoregion. It occurs on lower slopes and valley floors. Table 79 outlines features of the MQ1 Ecosite.

Table 79. General features of the MQ1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
MQ1	Fan, apron	Fluvial material B (calcareous, coarse-stratified)	Eutric Brunisol, Regosol	Engelmann spruce - subalpine fir closed and open forest (C15, O10)

Fluvial material A (noncalcareous, coarse stratified) occurs on some tracts. Veneers of Eolian material B (altered, medium textured) occur occasionally. Slopes range from 5 to

45% and are often channeled. Soils are well to moderately well drained.

WILDLIFE

Table 80. Wildlife features of the MQ1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
MQ1	high	deer moose elk	very high	wolf marten wolverine coyote cougar	medium	snowshoe hare columbian ground squirrel red squirrel	high

MQ1 is highly important to wildlife. The alluvial landforms are vegetated with a well developed shrub layer beneath the spruce-fir forest canopy which is forage for ungulates and cover for breeding birds. Deep snow limits large mammal activity in winter.

MANAGEMENT CONSIDERATIONS

Gently sloping MQ1 tracts dominated by Brunisolic soils generally have no limits for campgrounds, trails, or related park uses. However, Regosolic soils dominate some tracts where fluvial deposition is sufficiently frequent to maintain these weakly developed soils. This is the major factor in planning of certain park uses. Locally occurring coarse textures and high water tables present problems for sewage disposal. The coarse textured material provides gravel for construction purposes. The high content of coarse fragments may cause problems for some uses, e.g. trails, campgrounds, or playgrounds. Several tracts are locally avalanched, a factor to be considered for some uses.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

NG - NIGEL ECOSECTION

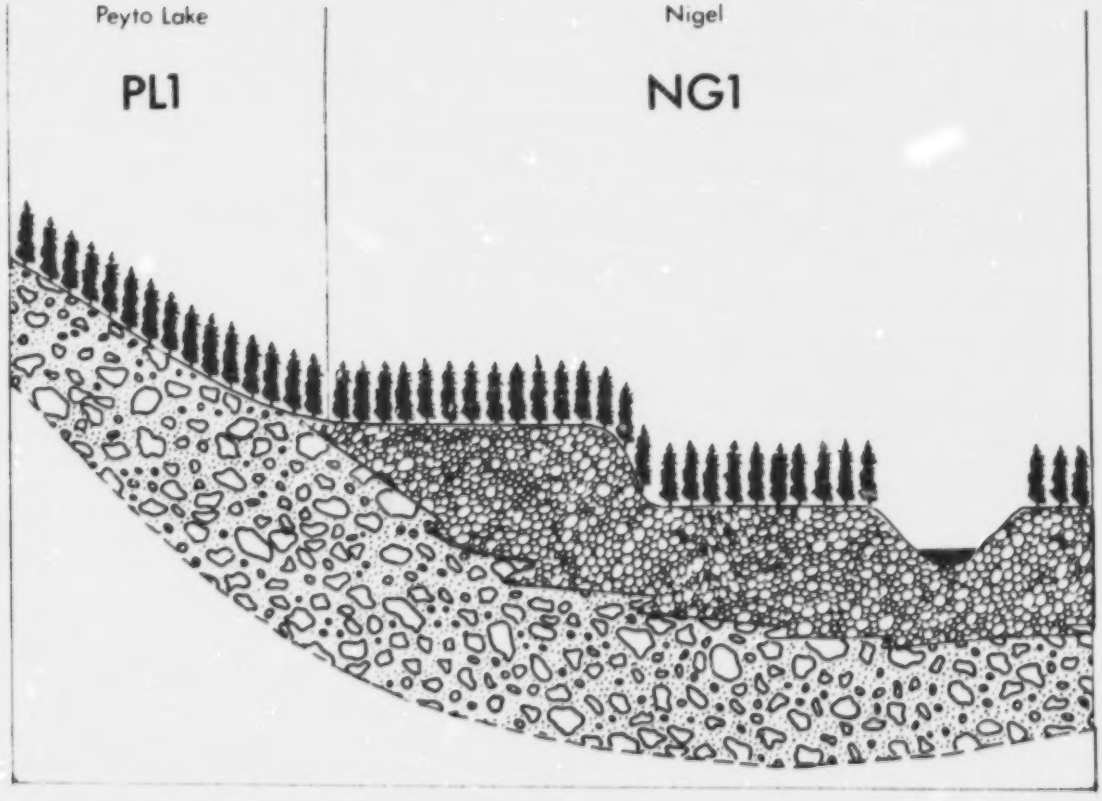
The Nigel (NG) Ecosection encompasses terraced landforms of calcareous glaciofluvial material in the Upper Subalpine portion of the Subalpine Ecoregion. It is dominated by soils under Engelmann spruce-subalpine fir closed and open forest. Table 81 outlines the features of the NG1 Ecosite. Landscape position is shown in Fig. 22.

Only two NG1 tracts were mapped, both in Banff. Thin veneers of Eolian material B (altered, medium textured) occur. Soils are well drained. NG1 occurs on valley floors. Slopes range from 1 to 15%.

Table 81. General features of the NG1 Ecosite.

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
NG1	Terraced	Glaciofluvial material B (calcareous, coarse textured)	Eutric Brunisol	Engelmann spruce - subalpine fir closed and open forest (C15, O10)

Fig. 22 Landscape schematic of the Nigel 1 (NG1) Ecosite.



WILDLIFE

NG1 is of low importance to wildlife except birds.

Table 82. Wildlife features of the NG1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
NG1	low		low		low		high

MANAGEMENT CONSIDERATIONS

NG1 is of very limited areal extent. Level topography and valley floor positions are conducive to many uses. Coarse textures provide gravel supplies. Coarse textured material is ineffective as an ion filter, a factor to be considered in sewage disposal system design. The coarse textures also promote droughtiness and problems in revegetation are likely to occur. The high content of coarse fragments may affect some uses, e.g. trails or campgrounds.

NH - NASHAN ECOSECTION

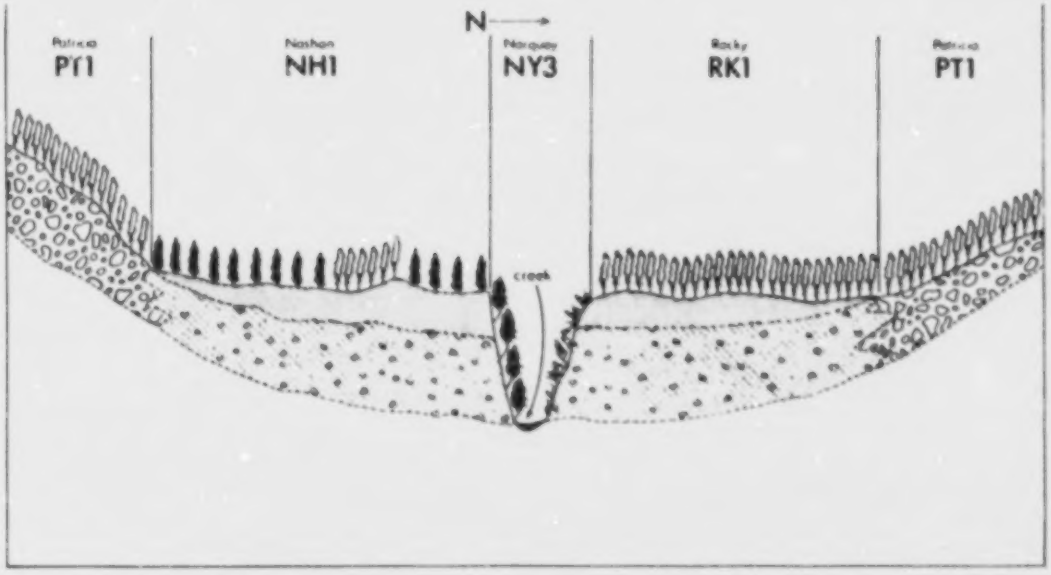
The Nashan (NH) Ecosection encompasses a wet > dry landscape pattern on glaciolacustrine landforms in the Montane Ecoregion. Wet (poorly drained) segments are dominated by Gleysolic soils under spruce open forest. Dry (well to moderately well drained) segments are dominated by Luvisolic and Brunisolic soils under lodgepole pine forest. Table 83 outlines the features of the NH1 Ecosite. Landscape position is shown in Fig. 23.

Table 83. General features of the NH1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
NH1	Glaciolacustrine blanket over undulating & hummocky glacial materials	Glaciolacustrine material (calcareous, fine textured)	Wet 80: Gleysol Dry 20: Gray Luvisol > Brunisol	Spruce open forest (O11) Lodgepole pine forest (C19, C29)

The glaciolacustrine material overlies Ice Contact Stratified Drift B (calcareous, variably textured). Wet segments usually have thin organic veneers of fen peat and veneers of Fluviolacustrine material A (altered, fine stratified). Dry segments have thin, discontinuous veneers of Eolian material B (altered, medium textured). Complex slopes range from 0 to 10%. NH1 occurs only in Jasper.

Fig 23 Landscape schematic of the Nashan 1 (NH1) Ecosite in relation to other Ecosites.



WILDLIFE

Table 84. Wildlife features of the NH1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
NH1	low	moose	medium	lynx	medium	pika red squirrel	medium

NH1 is moderately important to wildlife. Moose forage here extensively. Boreal species such as white-throated sparrow and spring peeper occur on this Ecosite of

limited area.

MANAGEMENT CONSIDERATIONS

Poor drainage, resulting from surface water collection on slowly pervious, fine textured, glaciolacustrine material, severely limits many park uses unless expensive construction techniques are followed.

NT - NUM-TI-JAH ECOSECTION

The Num-Ti-Jah (NT) Ecosection encompasses wet fluvial and fluviolacustrine landforms on col and valley floors in the Upper Subalpine portion of the Subalpine Ecoregion. Gleysolic soils characterize NT but Organic soils are also common on the NT3 Ecosite. The NT2 Ecosite has wet herb and moist shrub thicket vegetation, whereas NT3 has wet herb meadow, cottongrass fen, and sedge fen. Table 85 shows the landform, soil, and vegetational differences of the NT Ecosites. Landscape positions are shown in Figs. 20, 30 and 31.

Table 85. General features of the NT Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
NT2	Level, apron, fan	Fluvial materials A & B (noncalcareous & calcareous, coarse-stratified)	Gleysol	Wet shrub thicket (S8), moist shrub thicket (S4, S11)
NT3	Level, horizontal fen	Fluviolacustrine materials A & B (altered & calcareous, fine-stratified), fen peat	Gleysol, Mesisol	Wet herb meadow (H9), cottongrass fen (H10), sedge fen (H11)

Wetness on NT results from high water tables, seepage, and discharge, resulting in imperfectly to very poorly drained soils. Important accessory deposits include fluviolacustrine materials and fen peat for NT2, fluvial materials for NT3. Soils in active or recently active sedimentation environments lack surface peat layers, whereas soils of geomorphically inactive localities have surface organic layers and include Mesisols on horizontal fens in ponded localities. Although most NT3 tracts are ponded, recent geomorphic conditions favor organic material accumulation. Slopes are often channeled and range from 0 to 15% on NT2, 0 to 3% on NT3.

WILDLIFE

NT is moderately important to wildlife. High densities of small mammals occur on NT3. The Ecosection is used by all species of ungulates but is highly important to deer and moose. Critical winter habitat for white-tailed ptarmigan occurs where there are willow meadows.

Table 86. Wildlife features of the NT Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
NT2	low	deer moose	medium	coyote wolf	low	meadow vole columbian ground squirrel	low
NT3	low	deer moose	low	coyote wolf	high	meadow vole western jumping mouse	medium

MANAGEMENT CONSIDERATIONS

Imperfect to very poor drainage, resulting from high water tables and backwater flooding, severely limits most park uses unless expensive construction techniques are followed. On some NT tracts, sedimentation accompanies flooding. NT3 is of limited areal extent. Vegetation on NT3 is easily damaged and slow to recover from disturbances.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

NY - NORQUAY ECOSECTION

The Norquay (NY) Ecosection encompasses calcareous glacial landforms dominated by Brunisolic and Regosolic soils in the Montane Ecoregion. Vegetation includes lodgepole pine forest, Douglas fir open and closed forest, white spruce-Douglas fir forest, and low shrub-herb meadow. Two NY Ecosites are separaterd by genetic material differences and distribution patterns of soils and vegetation (Table 87). Landscape position is shown in Fig. 24.

NY1 occurs on lower valley walls; the linear surface form is considered depositional. Till B (noncalcareous, medium textured) dominates NY1 tracts mapped in the Miette River valley. Slopes range from 30 to 70% and are frequently gullied. Soil and vegetation patterns reflect surface erosional processes and moisture regime. Soils are rapidly to well drained.

NY3 occupies valley floor including benchland positions, usually adjacent to streams. Inclined surfaces are erosional (i.e. river banks), hummocky surfaces are depositional. Slopes range from 15 to 70% and are usually gullied. The pattern of soils and vegetation is governed by aspect, exposure, and erosional processes giving distinct northerly (well drained) versus southerly (rapidly drained) aspects.

WILDLIFE

NY is very important to wildlife. Critical range for deer, sheep and elk occurs on the open slopes. High densities of small mammals occur on dry areas. Associated with the concentrations of ungulates and small mammals are relatively high numbers of carnivores.

Table 87. General features of the NY Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
NY1	Blanket, veneer over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol > Regosol	Lodgepole pine forest (C6), Douglas fir forest (C1)
NY3	Inclined, hummocky	Ice contact stratified Drift B (calcareous, variably textured)	Northerly: Eutric Brunisol Southerly: Regosol	White spruce - Douglas fir forest (C5), lodgepole pine forest (C19). Douglas fir open and closed forest (O5, C1), low shrub-herb meadow (L1)

Fig. 24 Landscape schematic of the Norquay (NY) Ecosites in relation to other Ecosites.

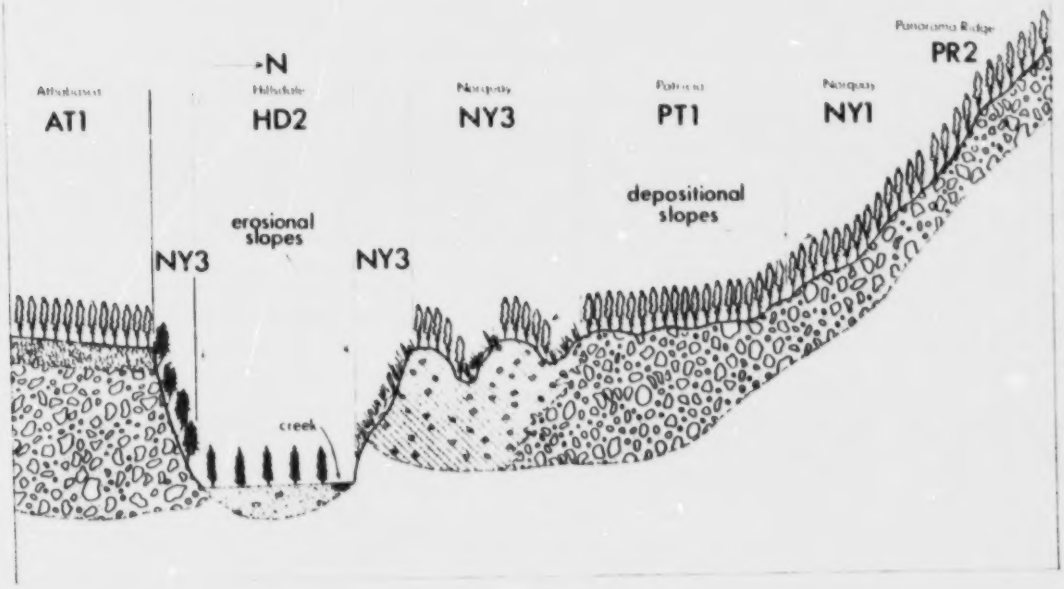


Table 88. Wildlife features of the NY Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
NY1	very high	deer bighorn sheep elk	high	wolf coyote cougar	high	columbian ground squirrel	medium
NY3	very high	deer elk bighorn sheep	very high	wolf coyote cougar marten	very high	red squirrel deer mouse heather vole long-tailed vole	high

MANAGEMENT CONSIDERATIONS

Steep and locally eroding slopes are limiting factors to be considered for most park uses on NY1 and NY3. Of particular concern on NY3 are the dry, southerly aspects where vegetation removal would increase erosion. Further, the subxeric vegetation of the southerly aspect segment is expected to recover slowly from disturbance. Coarse fragments may impose limitations to use of some slopes.

PL - PEYTO LAKE ECOSECTION

The Peyto Lake (PL) Ecosection encompasses calcareous morainal landforms dominated by Eutric Brunisols and coniferous forest in the Upper Subalpine portion of the Subalpine Ecoregion. Engelmann spruce-subalpine fir closed and open forest, subalpine larch-subalpine fir forest, a distinctive pattern of tundra plus coniferous open forest, and a dry > wet landscape pattern differentiate the four PL Ecosites as outlined in Table 89. Landscape positions are shown in Fig. 25.

PL occurs on valley walls, floors, and shoulders, and in cirque basins and cols. Slopes range from 5 to 70% and are often gullied on PL1. Veneers of Eolian material B (altered, medium textured) occur extensively in western Banff and southwestern Jasper, sporadically elsewhere. Podzolic soils are associated with the eolian veneers. Soils of PL1, PL3, PL4, and dry segments of PL5 are well to moderately well drained and imperfectly to poorly drained on wet segments of PL5. subalpine larch-subalpine fir/grouseberry-everlasting forest occurs only in southern Banff. Lithic soil phases are important on PL4 and PL5, turbic soil phases on PL4. Depressional segments of some PL5 tracts consist of Fluvial material B (calcareous, coarse-stratified).

WILDLIFE

PL is moderately important to wildlife. Large mammals rarely occur here in winter because of the deep snow. In contrast, some hibernating small mammals are very common.

Table 89. General features of the PL Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
PL1	Blanket over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol	Engelmann spruce - subalpine fir closed and open forest (C15, C21, O10)
PL3	Blanket over inclined, hummocky & ridged bedrock	Till C (calcareous, medium textured)	Eutric Brunisol > Humo-Ferric Podzol	Subalpine larch - subalpine fir forest (C23)
PL4	Blanket, veneer over inclined, hummocky & ridged bedrock	Till C (calcareous medium textured)	Eutric Brunisol > Melanic Brunisol, Ferro-Humic Podzol	Heath tundra (L5) > Engelmann spruce-subalpine fir open forest (O10)
PL5	Blanket, veneer over hummocky & ridged bedrock	Till C (calcareous medium textured)	Dry 70: Eutric Brunisol Wet 30: Gleysol, gleyed Podzolic & Brunisolic	Engelmann spruce - subalpine fir closed and open forest (C15, O10), subalpine larch-subalpine fir forest (C23) Wet shrub thicket (S8, S11)

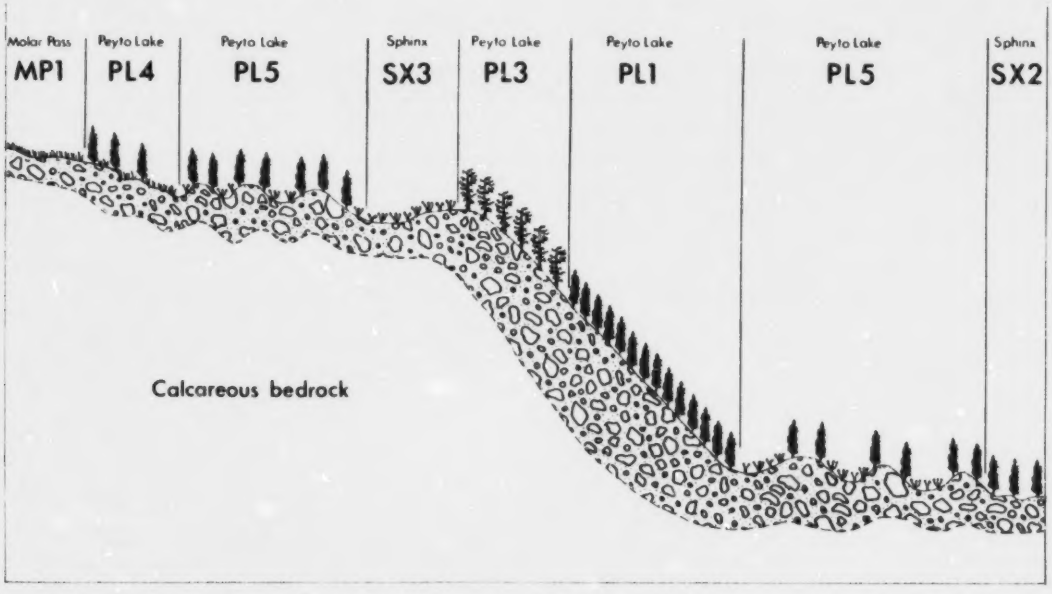
MANAGEMENT CONSIDERATIONS

The PL Ecosites can be treated as having similar responses to management, except for PL3 because of its limited areal extent and the wet segments of PL5 which necessitate special considerations for some uses (e.g. trail construction). Steepness of slope is the major factor to consider in planning of park uses. The eolian veneers, common in some areas, tend to erode easily where vegetation is removed. Locally occurring avalanche paths and occasional seeps will affect certain uses. Heath tundra vegetation on PL4 is slow to recover from disturbances.

PP - PIPESTONE ECOSECTION

The Pipestone (PP) Ecosection encompasses calcareous fluvial apron and fan landforms dominated by Regosolic soils in the Lower Subalpine portion of the Subalpine Ecoregion. Vegetation includes lodgepole pine forest, poplar forest, Engelmann spruce-subalpine fir open and closed forest, white spruce open forest, shrub thicket, shrubby meadow, and herb mat. Table 91 outlines six PP Ecosites separated primarily

Fig. 25 Landscape schematic of the Peyto Lake (PL) Ecosite in relation to other Ecosites.



on vegetational differences.

PP occurs on lower slopes and along streams on valley floors; channeling is a common surface feature. Slopes range from 2 to 45%; soils are rapidly to moderately well drained. Landforms are geomorphologically active and are subject to episodic flooding. PP2 is of limited areal extent and mapped only in Jasper. The majority of PP4 tracts occur close to the Continental Divide and are always found in close proximity to large glaciers or icefields. PP6 and PP7 tracts occur primarily in the Front Ranges.

WILDLIFE

The importance of this Ecosection to wildlife varies with each Ecosite. PP1, PP2, PP3 and PP4 are moderately important, while PP6 and PP7 are highly important. PP6 and PP7 have a well developed shrub and herb layer which increases their importance as foraging areas for ungulates and small mammals. Snow depths up to 1 m restrict ungulate use in winter.

MANAGEMENT CONSIDERATIONS

Management considerations are very similar for PP1, PP2, PP3, PP6 and PP7. Fluvial deposition is sufficiently frequent to maintain the Regosolic soils and is the major factor to consider when planning park uses. Locally occurring coarse textures and high

Table 90. Wildlife features of the PL Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
PL1	medium	caribou	high	marten weasel	low	pika columbian ground squirrel golden-mantled ground squirrel	low
PL3	low	deer	low	wolverine	high	least chipmunk heather vole meadow vole	low
PL4	medium	mountain goat bighorn sheep	medium	weasel wolverine cougar	medium	least chipmunk hoary marmot columbian ground squirrel red-backed vole	medium
PL5	medium	elk	medium	wolf coyote	medium	pika columbian ground squirrel heather vole	low

water tables present problems for sewage disposal, however coarse textured material provides gravel for construction purposes. PP2 is of limited areal extent. PP4 is somewhat different in that its level topography and valley floor positions are conducive to many uses. The active glaciofluvial environment of PP4 is subject to local flooding, high water tables, and shifting stream channels. The coarse textures require the same considerations as for the other PP Ecosites. Vegetation on PP4 can probably withstand moderate use but once destroyed is expected to recover slowly. Major construction activities (e.g. roads) will change sedimentation and erosion patterns on PP4.

EACH PP TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

PR - PANORAMA RIDGE ECOSECTION

The Panorama Ridge (PR) Ecosection encompasses calcareous glacial landforms dominated by a Brunisolic > Luvisolic soil complex and lodgepole pine forest within the Lower Subalpine portion of the Subalpine Ecoregion. Genetic material differences, episodic seepage, a northerly-southerly aspect landscape pattern, and vegetational differences separate the five PR Ecosites (Table 93). Landscape positions are shown in Fig. 26.

PR occurs on valley walls and floors including benchlands. Veneers of Eolian material B (altered, medium textured) occur locally especially in western Banff and southwestern Jasper. Slopes range from 15 to 70% and are often gullied except on PR3 where failed slopes are common. Soils of PR1, PR2, and PR6 are well drained; soils of PR3 are imperfectly drained and are affected by eposodic, near-surface seepage. PR4 landforms are erosional and the pattern of soils and vegetation is governed by northerly (well to moderately well drained) versus southerly (rapidly to well drained) aspects.

Table 91. General features of the PP Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
PP1	Fan, apron	Fluvial material B (calcareous, coarse -stratified)	Regosol	Lodgepole pine forest (C19, C3, C6)
PP2	Fan, apron	Fluvial material B (calcareous, coarse -stratified)	Regosol	Poplar forest (C16, C17)
PP3	Fan, apron	Fluvial material B (calcareous, coarse -stratified)	Regosol	Engelmann spruce-subalpine fir forest (C13, C31)
PP4	Fan, level	Glaciofluvial material B (calcareous, coarse textured)	Regosol	Herb mat (H8)
PP6	Fan, apron	Fluvial material B (calcareous, coarse -stratified)	Regosol	Engelmann spruce-subalpine fir open forest (O18), white spruce open forest (O17).
PP7	Fan, apron	Fluvial material B (calcareous, coarse-stratified)	Humic Regosol, Regosol	Shrubby meadow (S9), shrub thicket (S10)

WILDLIFE

PR is moderately important to wildlife. For some carnivores and many small mammals, most Ecosites are highly or very important. There is little forage to attract ungulates to this Ecosection and deep snow restricts most large mammal presence in winter.

MANAGEMENT CONSIDERATIONS

The PR1, PR2, and PR4 Ecosites have management concerns that are similar. Steepness of slope is the major factor to consider in planning of park uses. Locally occurring avalanche paths and seeps on PR1 and PR2, and locally eroding slopes on PR4 will affect certain uses.

Episodic, subsurface lateral water flow is the salient characteristic to be considered in planning park uses of PR3. The land surface is relatively dry, except for seeps, and presents no limits to low intensity uses on undisturbed surfaces. However, removal of surface and subsurface material may create seepage-induced slope failure. Slope failure is a common feature of PR3 and could be a continuing problem in some areas, e.g. a PR3/7c tract at Village Lake Louise in Banff that was investigated by TES Research and Consulting Ltd. (1973).

Table 92. Wildlife features of the PP Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
PP1	medium	elk	high	wolf coyote lynx cougar	medium	snowshoe hare columbian ground squirrel golden-mantled ground squirrel red squirrel red-backed vole	medium
PP2	medium	elk deer	very high	wolf weasel cougar	medium	dusky shrew red squirrel deer mouse meadow vole	medium
PP3	medium	moose	high	lynx	high	snowshoe hare golden-mantled ground squirrel deer mice porcupine	medium
PP4	medium	moose	medium		medium		low
PP6	high	moose elk	very high	wolf coyote weasel lynx cougar	high	snowshoe hare least chipmunk deer mouse	low
PP7	very high	moose elk	high	wolf cougar	low	columbian ground squirrel	low

PR6 has no characteristics limiting for campgrounds, trails, or related uses. Locally occurring coarse textured materials provide gravel sources but may present problems in sewage disposal due to ineffective ion filtration.

PT - PATRICIA ECOSECTION

The Patricia (PT) Ecosection encompasses calcareous glacial landforms dominated by Brunisolic and Luvisolic soils in the Montane Ecoregion. Vegetation is dominated by lodgepole pine and aspen forests. Four PT Ecosites are differentiated by vegetation, lithic soil phases, and a dry > wet landscape pattern (Table 95). Landscape positions are shown in Figs. 27 and 24.

PT occurs on valley floor benchlands; Ice Contact Stratified Drift B (calcareous, variably textured) is a significant constituent of some tracts. Veneers of Eolian material A (calcareous, medium textured) and Eolian material B (altered, medium textured) occur sporadically. Soils of PT1, PT3, PT4 and dry segments of PT5 are rapidly to well drained; poorly to very drained on wet segments of PT5. Bedrock outcrops are common on PT3. Slopes range from 2 to 70% and are usually complex.

Table 93. General features of the PR Ecosites.

Ecosite	Surface Expression	Genetic Material Unit	Soil	Vegetation
PR1	Blanket over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol > Gray Luvisol	Lodgepole pine forest (C11,C20, C29)
PR2	Blanket over inclined bedrock	Till C (calcareous, medium textured)	Eutric Brunisol > Gray Luvisol	Lodgepole pine/ buffaloberry (C6, C18, C19)
PR3	Blanket over inclined & hummocky bedrock, hummocky	Till C (calcareous, medium textured)	Gleyed Eutric Brunisol > gleyed Gray Luvisol	Lodgepole pine/ buffaloberry (C18, C19)
PR4	Inclined	Till C (calcareous, medium textured) and Ice contact stratified Drift B (calcareous, variably textured)	Northerly: Eutric Brunisol Southerly: Eutric Brunisol > Gray Luvisol, Regosol	Engelmann spruce - subalpine fir forest (C13, C14) Lodgepole pine forest (C3, C6, C19)
PR6	Blanket over inclined & hummocky bedrock, hummocky	Ice contact stratified Drift B (calcareous, variably textured)	Eutric Brunisol > Gray Luvisol	Lodgepole pine forest (C11, C18, C19, C29)

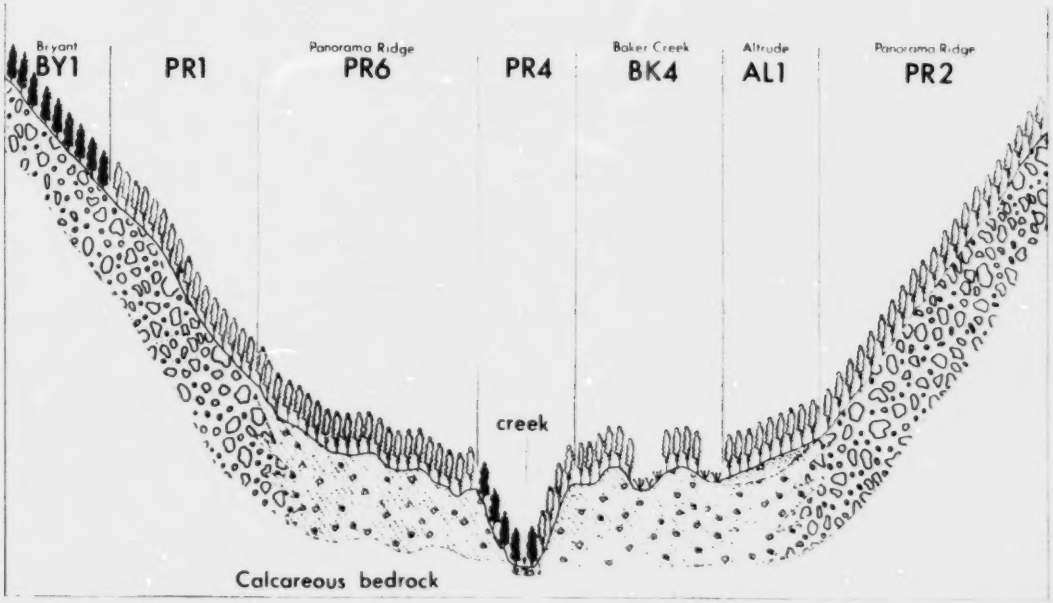
WILDLIFE

PT is highly important to wildlife. Located in the warmer Montane zone with low snow acumulation, it is winter range for elk and deer. Some small mammals, especially red squirrels, occur here in large numbers while carnivores also concentrate here. Breeding bird densities are high to very high.

MANAGEMENT CONSIDERATIONS

The PT Ecosites can all be treated similarly regarding management concerns, except for PT4 because of its limited areal extent. Also, the wet segments of PT5 necessitate special considerations for some uses (e.g. trail construction). Tracts with gentle slopes generally have no characteristics limiting for park uses. Moderate to steep, irregular slopes with shallow soils and bedrock outcrops are major factors in planning park uses, especially on PT3 where colluviation is common on exceptionally steep south facing slopes. The textural variability of ice contact stratified drift, common on some valley floor tracts, may influence some uses.

Fig. 26 Landscape schematic of the Panorama Ridge (PR) Ecosite in relation to other Ecosites.



RD - REDOUBT ECOSECTION

The Redoubt (RD) Ecosection (Table 97) encompasses inclined, noncalcareous, medium textured colluvium in the Alpine Ecoregion. Soils are Dystric and Sombric Brunisols, Regosolics, and Humic Regosols. Vegetation is characterized by mountain avens tundra and heath tundra. Landscape position is shown in Figs. 20 and 31.

RD1 occurs on steep, usually linear slopes in areas that are geologically dominated by Miette Group in the Main Ranges or noncalcareous Mesozoic strata in the Front Ranges. Colluvial processes are locally active and include avalanching, soil creep, cryoturbation and solifluction. Slopes range from 45 to 70%. Soils are well drained. Unvegetated portions may constitute up to 50% of RD1 tracts.

WILDLIFE

RD1 is moderately important to wildlife but highly important for sheep, goats and some small mammals. In winter these areas are frequently blown free of snow allowing ungulates to graze easily.

Table 94. Wildlife features of the PR Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
PR1	low	deer	high	wolf wolverine	low	columbian ground squirrel golden-mantled ground squirrel	high
PR2	medium	elk	very high	marten weasel lynx wolf coyote cougar	medium	snowshoe hare columbian ground squirrel golden-mantled ground squirrel red squirrel red-backed vole	low
PR3	medium	moose	medium		high	red-backed vole long-tailed vole	medium
PR4	medium		high	coyote marten wolverine	very high	golden-mantled ground squirrel red squirrel deer mouse red-backed vole long-tailed vole western jumping mouse	medium
PR6	medium	deer	high	marten lynx wolf coyote cougar	medium	snowshoe hare porcupine	medium

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting factors for many park uses. Slope failure is a feature of some RD1 tracts. Potential for slope failure is unknown. Removal of vegetation will result in wind, water, and gravity erosion. Vegetation is expected to recover slowly from disturbances.

RK - ROCKY ECOSECTION

The Rocky (RK) Ecosection encompasses glaciolacustrine landforms dominated by Luvisolic and Brunisolic soils and lodgepole pine forest in the Montane Ecoregion (Table 99). Landscape position is shown in Fig. 23.

RK1 is mapped only in Jasper and occurs on valley floor benchlands. The glaciolacustrine material overlies Ice Contact Stratified Drift B (calcareous, variable textured). Surficial veneers of Eolian material B (altered, medium textured) occur on some tracts. Slopes range from 2 to 10%. Soils are well to moderately well drained.

WILDLIFE

Table 95. General features of the PT Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
PT1	Ridged & hummocky including bedrock control (blanket)	Till C (calcareous, medium textured)	Eutric Brunisol, Gray Luvisol	Lodgepole pine forest (C6,C19)
PT3	Veneer over ridged bedrock - ridged bedrock	Till C (calcareous, medium textured	Eutric Brunisol - Gray Luvisol (lithic phases)	Lodgepole pine forest (C3, C6, C19)
PT4	Ridged including bedrock control (blanket)	Till C (calcareous, medium textured)	Eutric Brunisol, Gray Luvisol	Aspen forest (C16)
PT5	Ridged - horizontal fen	Till C (calcareous, medium textured) - fen peat	Dry 60: Eutric Brunisol, Gray Luvisol Wet 40: Glevsol Mesisol	Lodgepole pine forest (C6, C11, C19) Black spruce-lodgepole pine forest (C8), spruce open forest

Table 96. Wildlife features of the PT Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
PT1	high	deer elk	high	coyote cougar wolf	high	red squirrel red-backed vole	high
PT3	high	deer moose elk	high	cougar wolf coyote	high	red squirrel deer mouse big brown bat	high
PT4	medium	deer bighorn sheep elk	high	wolf coyote cougar	high	red squirrel meadow vole	very high
PT5	medium	deer	high	coyote cougar lynx wolf	medium	snowshoe hare red squirrel meadow vole	high

RK 1 is moderately important to wildlife overall but very important to small mammals.

MANAGEMENT CONSIDERATIONS

Although considered to be dry (well to moderately well drained), the slow infiltration and permeability rates of the fine textured glaciolacustrine material will create problems where water can collect (e.g. depressions on trails). Removal of vegetation will significantly increase the chances for water and wind erosion, including slumps.

Fig. 27 Landscape schematic of the Patricia (PT) Ecosites in relation to other Ecosites.

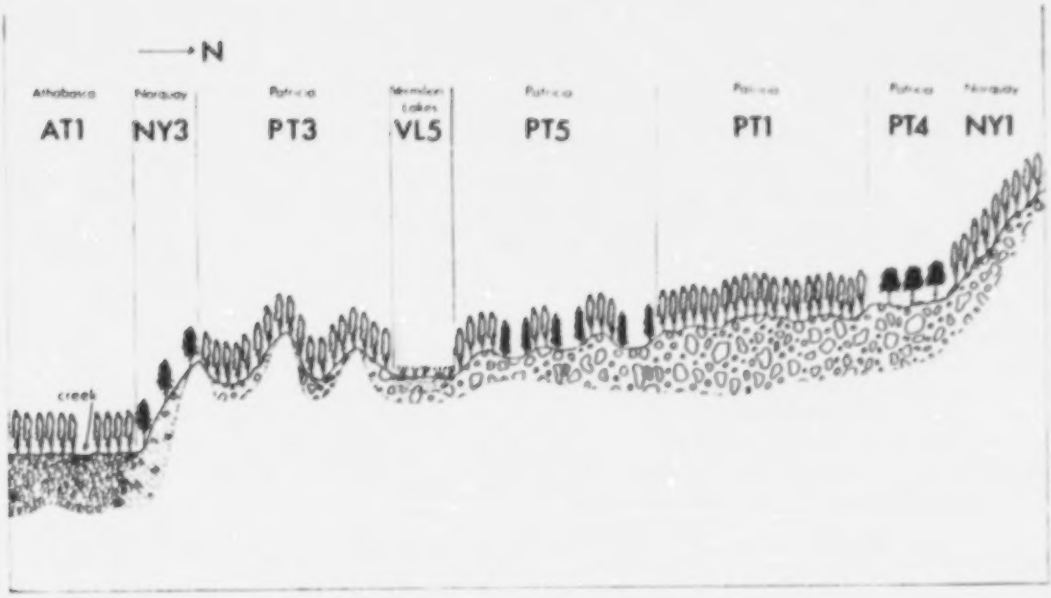


Table 97. General features of the RD1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation

RK1	Glaciolacustrine blanket over undulating & hummocky glacial materials	Glaciolacustrine material (calcareous, fine textured)	Gray Luvisol > Eutric Brunisol	Lodgepole pine forest (C19, C29)

SB - SAWBACK ECOSECTION

The Sawback (SB) Ecosection encompasses inclined landforms of calcareous, medium textured colluvium in the Lower Subalpine portion of the Subalpine Ecoregion. Brunisolic and Regosolic soils dominate under avalanche complex v.t.s., Engelmann spruce-subalpine fir forest, lodgepole pine forest, coniferous open forest, shrub-herb meadow, and grassland. The five SB Ecosites are separated primarily by vegetational features (Table 101). Landscape positions are shown in Figs. 28 and 29.

SB occurs on or below steep valley walls and is associated with calcareous bedrock. Slopes generally range from 45 to 100% and snow avalanching characteristically affects more than 50% SB1. Soils are rapidly to moderately well drained. Unvegetated portions constitute up to 50% of some SB1 and SB4 tracts. SB5 occurs primarily in the Front Ranges on dry, southerly aspects. SB4 is the steepest of the five SB Ecosites and has the greatest abundance of lithic soils and bedrock outcrops. Avalanche Compex 1, for SB1, is a heterogeneous complex of v.t.s. that includes subalpine fir-willow (S2), willow-dwarf birch-shubby cinquefoil (S10), hairy wild rye-wild strawberry-fireweed (H5), aspen/hairy wild rye-showy aster (C22), plus intergrades, with S2 and H5 being most abundant.

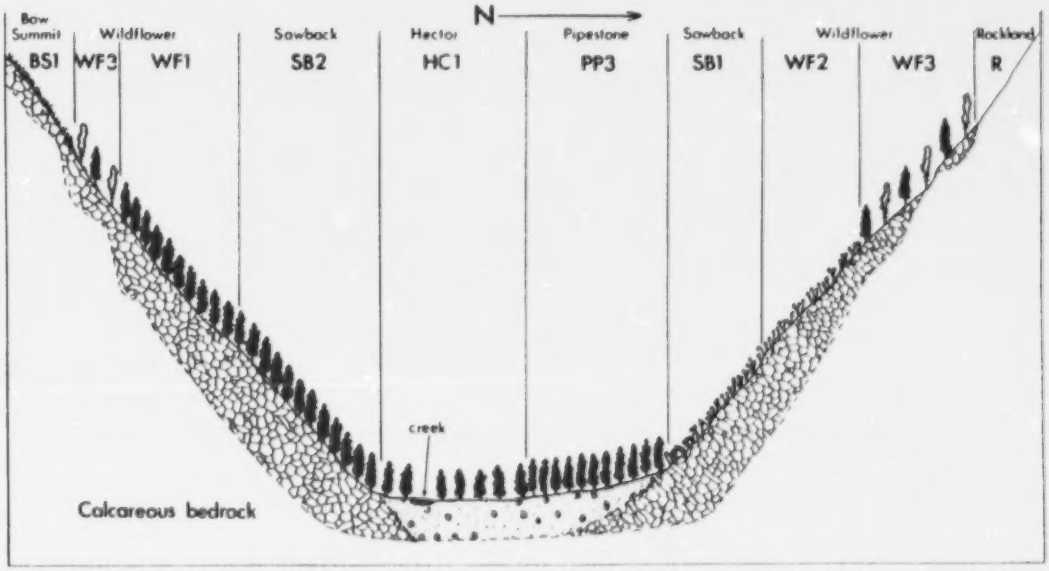
SB4	medium	mountain goat bighorn sheep	low	cougar	medium	pika least chipmunk	medium
SB5	very high	bighorn sheep deer elk mountain goat	medium	cougar wolf coyote	medium	deer mouse	low

Fig. 28 Landscape schematic of the Sawback Ecosites in relation to other Ecosites.



SB is highly important for wildlife. Critical winter range for sheep and goats occurs here as well as high densities of some small mammals, birds and carnivores. Located in the Front Ranges, SB Ecosites do not receive much snow and consequently ungulates can easily crater for forage, especially on SB5.

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting factors to be considered for many park uses. Snow avalanching, whether local (on SB2, SB3, SB4) or extensive (SB1), will affect winter uses. Shallow soils and bedrock outcrops on SB4 are factors to be considered when planning certain uses (e.g. trails). It is expected that vegetation on SB4 and SB5 recovers slowly from disturbances and that vegetation removal on SB5 will significantly increase erosion, particularly colluviation. Droughty conditions on SB5 will compound potential revegetation problems.

SF - SNOWFLAKE ECOSECTION

The Snowflake (SF) Ecosection (Table 103) encompasses morainal landforms dominated by Cryosolic soils and Engelmann spruce–subalpine fir forest in the Upper Subalpine portion of the Subalpine Ecoregion. The SF Ecosection develops on northerly aspects in the Front Ranges of both Banff and Jasper, from Banff townsite northwestward. Landscape position is shown in Fig. 29.

Table 103. General features of the SF1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
SF1	Blanket over inclined bedrock	Till B & C (noncalcareous & calcareous, medium textured)	Static Cryosol >Gleyed Eutric Brunisol	Engelmann spruce - subalpine fir forest (C13, C24)

SF1 occurs on valley wall slopes and is associated with materials derived from Mesozoic strata. Failed and soliflucted slopes are common; slopes range from 30 to 70%. The Cryosolic soils are frozen to within 1 m of the surface throughout the year. The soils are imperfectly drained. The Engelmann spruce–subalpine fir/rock willow/white mountain heather v.t. is more abundant than Engelmann spruce–subalpine fir/feather-moss forest.

WILDLIFE

Table 104. Wildlife features of the SF1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
SF1	high	elk	medium	wolf cougar	medium	snowshoe hare red-backed vole porcupine	medium

SF1 is moderately important to all groups of wildlife. It is most important to large mammals in summer. Snow depths up to 0.8 m restrict large mammal movement in winter.

MANAGEMENT CONSIDERATIONS

Permafrost and solifluction in the active layer are the two main features that limit park uses to activities that do not disturb the insulation and thermal balance. Removal of vegetation and surface organic layers will increase the active layer depth, possibly resulting in slope failure. Road construction, in particular, should avoid SF1 tracts.

SP - SPRAY ECOSECTION

The Spray (SP) Ecosection encompasses glaciolacustrine landforms dominated by Luvisolic and Brunisolic soils and lodgepole pine forest in the Lower Subalpine portion of the Subalpine Ecoregion. Table 105 outlines the features of the SP1 Ecosite.

SP1 occupies valley floor and lower slope positions. Surficial veneers of Eolian

Fig. 29 Landscape schematic of the Snowflake 1 (SF1) Ecosite in relation to other Ecosites.

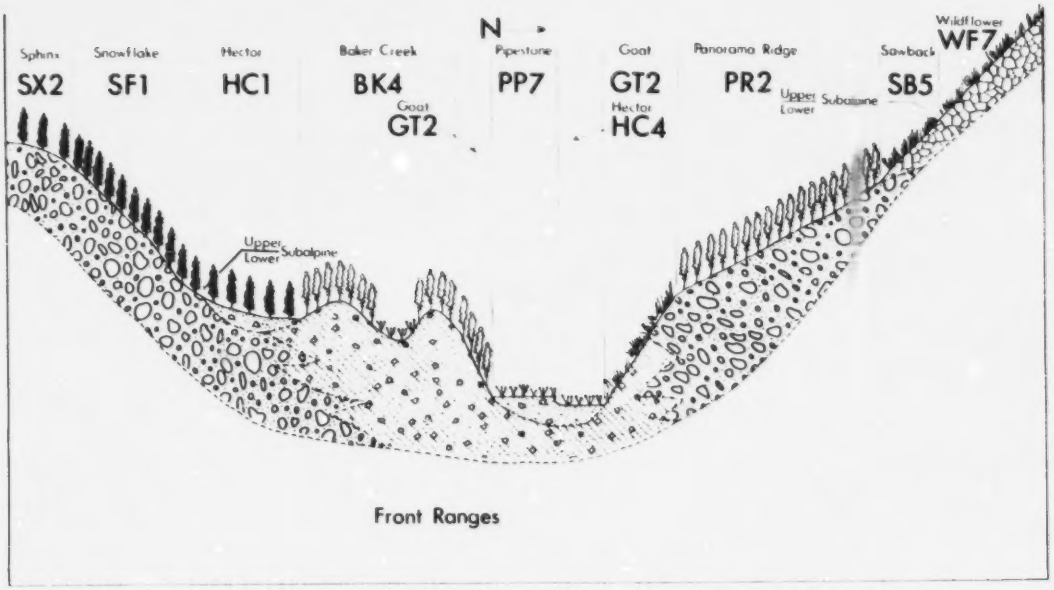


Table 105. General features of the SP1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
SP1	Glaciolacustrine veneer & blanket over undulating & hummocky glacial materials	Glaciolacustrine material (calcareous, fine textured) over Ice contact stratified Drift B (calcareous, variably textured)	Gray Luvisol, Eutric Brunisol	Lodgepole pine forest (C18, C19)

material B (altered, medium textured) occur occasionally. Slopes are between 2 and 15%. Soils are well to moderately well drained. On some SP1 tracts Till C (calcareous, medium textured) underlies the glaciolacustrine material.

WILDLIFE

Table 106. Wildlife features of the SP1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
SP1	medium	elk	medium	cougar	low	red squirrel	medium

This Ecosite is moderately important to wildlife. However, very few species occur here in high numbers. Snow depths up to 1.2 m restrict ungulate movement in winter.

MANAGEMENT CONSIDERATIONS

Even though SP1 is well to moderately well drained, the slow infiltration and permeability rates of the glaciolacustrine material will create problems wherever water can collect (e.g. depressions on trails). Removal of vegetation will significantly increase the chances for water and wind erosion, including slumps.

SX - SPHINX ECOSECTION

The Sphinx (SX) Ecosection encompasses moist to wet morainal landforms in the Upper Sublapine portion of the Subalpine Ecoregion. Soils are genetically related Gleysolics, gleyed Podzolics, and gleyed Brunisolics. Vegetation reflects varying seepage conditions and includes moist herb meadow, dwarf shrub-herb meadow, heath tundra, moist shrub thicket, wet shrub thicket, and Engelmann spruce-subalpine fir open forest. Table 107 outlines the features of the three SX Ecosites, seperated primarily by vegetational differences.

SX occurs on floors, benchlands, walls, and shoulders within valleys, cols, and cirques. Wetness is attributed to seasonal and episodic seepage giving imperfectly to poorly drained soils. The discontinuous fluviolacustrine material was derived locally by sheet erosion of morainal surfaces and reworking of postglacial eolian deposits. Solifluction is common, especially on SX1, and contributes to the occurrence of turbic phase soils. Slopes range from 5 to 45%.

WILDLIFE

SX is moderately important to wildlife. Some small mammals reach very high densities on SX Ecosites and, in addition, SX supports many species of small mammals. In summer, many areas in Jasper are highly important range for caribou. In winter, snow is too deep for ungulates to occur here.

Table 107 General features of the SX Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
SX1	Morainal blanket over inclined, hummocky, to ridged bedrock > fluviolacustrine veneer	Till B (noncalcareous, medium textured) > Fluviolacustrine material A (altered, fine-stratified)	Gleysol, gleyed Podzolic, Gleyed Dystric Brunisol	Moist herb meadow (H16), dwarf shrub-herb meadow (L7) > heath tundra (L5), wet shrub thicket (S8)
SX2	Morainal blanket over inclined, hummocky, & ridged bedrock > fluviolacustrine veneer	Till B & C (noncalcareous & calcareous, medium textured) > Fluviolacustrine material A (altered, fine-stratified)	Gleysol, gleyed Podzolic, Gleyed Dystric Brunisol	Engelmann spruce - subalpine fir open forest (09,010)
SX 3	Morainal blanket over inclined, hummocky & ridged bedrock > fluviolacustrine veneer	Till B & C (noncalcareous & calcareous, medium textured) > Fluviolacustrine material A (altered, fine-stratified)	Gleysol, gleyed Podzolic, Gleyed Eutric Brunisol	Moist shrub thicket (S4), wet shrub thicket (S8)

Table 108. Wildlife features of the SX Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
SX1	low	caribou	medium	weasel	high	dusky shrew hoary marmot columbian ground squirrel northern bog lemming long-tailed vole porcupine	low
SX2	medium	moose	high	marten weasel wolverine wolf coyote	medium	masked shrew columbian ground squirrel red-backed vole heather vole porcupine	medium
SX3	high	caribou bighorn sheep	medium		medium	beaver	high

MANAGEMENT CONSIDERATIONS

Imperfect to poor drainage resulting from seepage is the major factor limiting most park uses. Moist, herb dominated v.t.s may be expected to recover quickly after moderate disturbances but will not tolerate heavy or prolonged use. Solifluction is common locally and may limit some uses. Removal of vegetation is expected to increase erosion, particularly solifluction.

TA - TALBOT ECOSECTION

The Talbot (TA) Ecosection encompasses surficial eolian veneers overlying glacial deposits in the Montane Ecoregion. Regosolic soils dominate under white spruce forest, grassland, and low shrub-herb meadow vegetation. Table 109 separates the two TA Ecosites, primarily by vegetational differences. Landscape positions are shown in Fig. 16.

Table 109. General features of the TA Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
TA2	veneer over inclined bedrock	Eolian material A (calcareous, medium textured)	Regosol	Grassland (H6), low shrub-herb meadow (L1)
TA3	Veneer over glacial blanket over hummocky and ridged bedrock	Eolian material A (calcareous, medium textured) over Ice contact stratified Drift B (calcareous, variably textured).	Regosol > Eutric Brunisol	White spruce forest (C2, C26, C27)

TA occurs on lower slopes and benchlands of major river valleys. Slopes range from 30 to 70% on TA2, from 5 to 70% on TA3. Soils are extremely calcareous and rapidly to well drained. TA2 occurs only in Jasper and is most common on southerly and easterly facing erosional scarps. The white spruce/fern moss and white spruce/prickly rose/fern moss v.t.s of TA3 occur only in Jasper.

WILDLIFE

This Montane Ecosection is very important to wildlife. The grasslands are critical winter range for elk, deer and sheep in many areas. Very high densities of deer mice occur on TA2. Wolf, cougar, and coyote are attracted by the high prey densities. The relatively warm climate, shallow snow accumulation and patches of forest enhance attractiveness of to wildlife.

MANAGEMENT CONSIDERATIONS

Regosolic soils dominate and indicate current and recent eolian deposition. Removal of vegetation is likely to result in wind and water erosion. Steep slopes and droughty conditions compound such potential erosion problems. Vegetation of TA3 is more resilient than that of TA2, but removal of vegetation is also expected to result in wind and water erosion, particularly on steep slopes.

Table 110. Wildlife features of the TA Ecosites

Ecosite	Ungulates		Carnivores		Small Mammals		Birds
	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
TA2	very high	bighorn sheep mountain goat deer	medium	wolf cougar coyote	very high	deer mouse heather vole	medium
TA3	very high	elk bighorn sheep deer moose	high	cougar wolf coyote marten	medium	red squirrel	high

TK - TEKARRA ECOSECTION

The Tekarra (TK) Ecosection (Table 111) encompasses inclined landforms of noncalcareous, coarse textured colluvium in the Alpine Ecoregion. Dystric and Sombric Brunisols and Regosolics occur under heath tundra and mountain avens tundra.

Table 111. General features of the TK1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
TK1	Blanket, veneer over inclined bedrock	Colluvium A (noncalcareous, coarse textured)	Dystric & Sombric Brunisol, Regosol	Heath tundra (L5), mountain avens tundra (H1)

TK1 occurs on steep, usually linear slopes in Main Ranges areas that are geologically dominated by Gog Group quartzites. Surface veneers of Eolian material B (altered, medium textured) occur sporadically. Slopes commonly range from 45 to 100%. Soils are well drained. Colluvial processes are locally active and include avalanching and soil creep. Unvegetated portions may constitute up to 50% of TK1 tracts.

WILDLIFE

TK is of low importance to wildlife.

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting factors to be considered for many park uses. Removal of vegetation is likely to result in water and gravity erosion. Vegetation is expected to recover slowly from disturbances. Stony surfaces (coarse fragments) will affect certain uses such as trails.

Table 112. Wildlife features of the TK1 Ecosite

Ecosite	Ungulates		Carnivores		Small Mammals		Birds
	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
TK1	low		low		low	pika	medium

TR - TYRRELL ECOSECTION

The Tyrrell (TR) Ecosection encompasses dry to moist, shrubland and grassland dominated, morainal landforms in the Upper Subalpine portion of the Subalpine Ecoregion. Both calcareous and noncalcareous, medium textured tills form the moraines. Soils are Eutric and Melanic Brunisols. The features of the two TR Ecosites are outlined in Table 113. Landscape positions are shown in Fig. 30.

Table 113. General features of the TR Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
TR1	Blanket, veneer over inclined, hummocky & ridged bedrock	Till B & C (non-calcareous & calcareous, medium textured)	Eutric Brunisol > Melanic Brunisol	Dry shrub thicket (S10), moist shrub thicket (S12), Engelmann spruce-subalpine fir open forest (O18)
TR2	Blanket, veneer over inclined, hummocky & ridged bedrock	Till B & C (non-calcareous & calcareous, medium textured)	Eutric & Melanic Brunisol	Grassy tundra (H4), dry grassland (H14)

TR occurs on most topographic positions and is most extensive in the Front Ranges in association with Mesozoic and adjacent strata. Wet terrain is important on some TR1 tracts where it is associated with fluvial materials along streams. Slopes generally range from 5 to 45% on TR1 and from 30 to 70% on TR2. Tundra vegetation, including the mountain avens-snow willow-moss campion, mountain avens-kobresia-bearberry, white mountain heather-mountain avens-snow willow and heather-everlasting v.t.s, is important locally on TR1. Exposure, steepness of slope, and southerly aspects account for the dominant grassy vegetation on TR2.

WILDLIFE

TR is highly important to wildlife, particularly large mammals in summer. In winter, deep snow precludes large mammal activity in many areas.

Fig. 30 Landscape schematic of the Tyrrell (TR) Ecosites in relation to other Ecosites

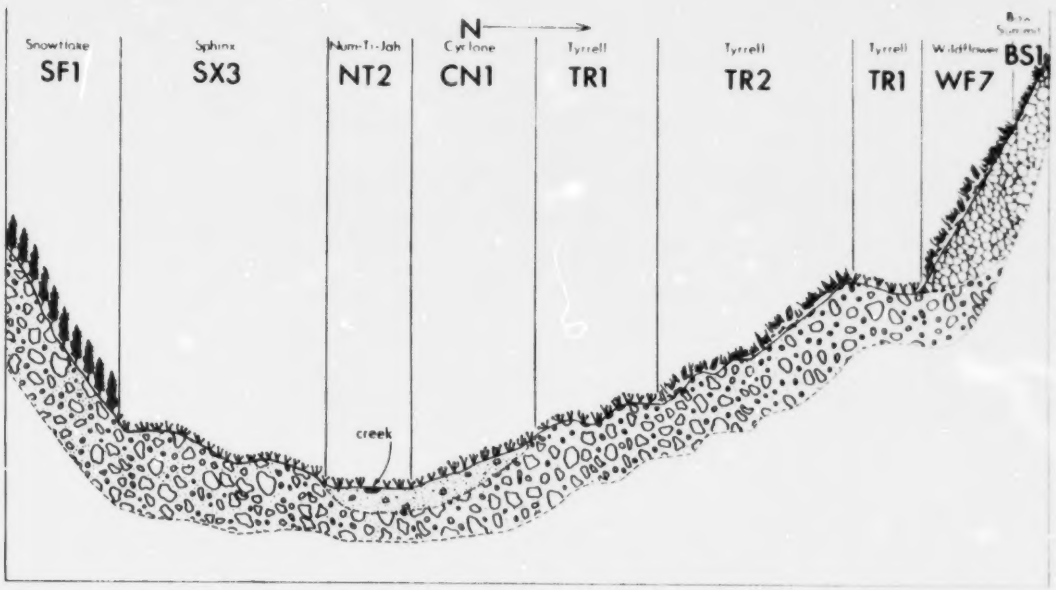

Table 114. Wildlife features of the TR Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
TR1	high	elk bighorn sheep	high	coyote wolf cougar	medium	least chipmunk hoary marmot	medium
TR2	high	elk bighorn sheep mountain goat caribou	high	coyote weasel cougar wolf	low		medium

MANAGEMENT CONSIDERATIONS

TR1 tracts with gentle slopes have no outstanding features limiting for park uses. Problems may arise with locally occurring features such as the complex tundra vegetation on hummock and ridge crests, wet terrain on depressional localities, and solifluction and cryoturbation on seepage affected sites.

On TR2 tracts, steepness of slope is the major factor to consider in planning of park uses. The degree of vegetation fragility is not known, but it is expected that vegetation recovers slowly after disturbance and that vegetation removal will significantly increase the chances of erosion. Droughty conditions compound potential revegetation problems.

TZ - TOPAZ ECOSECTION

The Topaz (TZ) Ecosection encompasses glacial and glaciofluvial landforms comprised of noncalcareous, coarse textured, ice contact stratified and glaciofluvial materials within the Lower Subalpine portion of the Subalpine Ecoregion. TZ is dominated by Dystric Brunisols and lodgepole pine forest. The features of the two TZ Ecosites, separated on the occurrence of a dry > wet versus an all dry landscape pattern, are outlined in Table 115. Landscape positions of the TZ Ecosites are shown in Fig. 8.

Table 115. General features of the TZ Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
TZ1	Ridged, hummocky & terraced	Ice contact stratified Drift A & Glaciofluvial material A (noncalcareous, coarse textured)	Dystric Brunisol	Lodgepole pine forest (C35, C19)
TZ2	Ridged, hummocky	Ice contact stratified Drift A (noncalcareous, coarse textured)	Dry 70: Dystric Brunisol Wet 30: Gleysol > Mesisol	Lodgepole pine forest (C35, C19) Wet Engelmann spruce - subalpine fir open forest (06), wet spruce open forest (011), wet shrubby meadow (S1), birch fen (S3)

TZ occurs on valley floors and lower slopes in the Main Ranges in Jasper, usually in association with Gog Group (quartzite) bedrock. Slopes range from 2 to 45% and are frequently channeled. Soils of the dry upland portions are rapidly drained; soils of wet depressions of TZ2 are imperfectly to very poorly drained. Lower B horizons of dry soils are often weakly cemented (duric tendency).

WILDLIFE

TZ is of moderate importance to wildlife. Only some small mammals occur here in high densities.

Table 116. Wildlife features of the TZ Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
TZ1	low		medium		medium	red squirrel red-backed vole heather vole	medium
TZ2	low		medium		low	snowshoe hare porcupine	low

MANAGEMENT CONSIDERATIONS

Both TZ Ecosites are of limited extent. Valley floor tracts with gentle slopes are convenient for many park uses, but other features should be considered. Coarse textured material provides gravel and sand for construction purposes, but such coarse textures are ineffective ion filters and thus present problems in sewage disposal. Abundant lichen vegetation occurs in some areas and is thought to be easily damaged and slow to recover from disturbances. Stony surfaces in some localities will affect trail and campsite construction. Characteristic dry > wet landscape pattern of TZ2 necessitates special considerations in planning certain park uses (e.g. trails).

VD - VERDANT ECOSECTION

The Verdant (VD) Ecosection encompasses fan and apron landforms consisting of noncalcareous, fluvial material within the Lower Subalpine portion of the Subalpine Ecoregion. It is dominated by Brunisolic soils with either spruce or pine forests. Table 117 outlines features of the VD Ecosites.

Table 117. General features of the VD Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
VD1	Fan, apron	Fluvial material A (noncalcareous, coarse-stratified)	Dystric Brunisol	Engelmann spruce-subalpine fir forest (C13, C14)
VD2	Fan, apron	Fluvial material A (noncalcareous, coarse-stratified)	Dystric Brunisol	Lodgepole pine forest (C19, C20)

VD occurs on lower slopes and valley floors. Veneers of Eolian material B (altered, medium textured) occur occasionally. Linear slopes between 2 and 30% are characteristic. Soil development reflects recent geomorphic stability. Soils are well to

moderately well drained.

WILDLIFE

Table 118. Wildlife features of the VD Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
VD1	low	moose	high	weasel lynx	high	snowshoe hare red squirrel red-backed vole	low
VD2	low	moose	high	marten weasel wolverine	low		low

VD is moderately important to wildlife. It is highly important to carnivores but of low importance to ungulates, birds and some small mammals.

MANAGEMENT CONSIDERATIONS

VD1 and VD2 tracts with gentle slopes generally have no characteristics limiting for campgrounds, trails, and related park uses. Locally occurring coarse textures and high water tables may present problems for sewage disposal, but the coarse textured material provides gravel for construction purposes.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

VL - VERMILION LAKES ECOSECTION

The Vermilion Lakes (VL) Ecosection encompasses wet fluvial and fluviolacustrine landforms on valley floors in the Montane Ecoregion. Gleysolic soils are characteristic but Organic soils and gleyed Regosol soils are common on some VL Ecosites. Vegetational features differentiate the four VL Ecosites (Table 119).

Wetness on VL results from high water tables and backwater flooding which causes imperfectly to very poorly drained soils. Fluvial material B on VL is low in coarse fragments. A low lime phase of Fluvial material B occurs in the Miette and Athabasca River valleys upstream from Jasper townsite. The interbedding of fluvial and fluviolacustrine materials on several VL Ecosites illustrates the dynamics of depositional environments over time. Soils in active or recently active sedimentation environments lack surface peat layers, whereas soils of geomorphically inactive localities have surface organic layers and include Mesisols on horizontal fens in ponded localities. VL1 and VL5 have the most abundant geomorphically active terrain. Slopes commonly range from 0 to 2% and are often channeled. VL1 is often ponded and small water bodies are common.

Table 119. General features of the VL Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
VL1	Level, horizontal fen	Fluviolacustrine material B (calcareous, fine-stratified), fen peat	Gleysol, Mesisol	Sedge fen (H11), wet shrubby meadow (S1), wet shrub thicket (S7)
VL3	Level	Fluvial material B (calcareous, coarse-stratified), Fluviolacustrine material B (calcareous, fine-stratified)	Gleysol	Wet white spruce forest (C4) > shrubby meadow (S1), wet shrub thicket (S7)
VL4	Level, apron, fan	Fluvial material B (calcareous, coarse-stratified), Fluviolacustrine material B (calcareous, fine-stratified)	Gleysol	Wet white spruce forest (C4)
VL5	Level, apron, fan	Fluvial material B (calcareous, coarse-stratified), Fluviolacustrine material B (calcareous, fine-stratified)	Gleysol > Gleyed Regosol	Wet shrub thicket (S7)

WILDLIFE

VL is very important to wildlife and is one of the most important in the two national parks. Critical winter range for elk and moose occurs here and many small mammal species reach high densities. Carnivores are attracted by these prey. Numerous bird species occur in the wetlands in high densities and many do not occur elsewhere in the parks. Uncommon raptors such as osprey and bald eagle nest in VL.

MANAGEMENT CONSIDERATIONS

Imperfect to very poor drainage, resulting from high water tables and backwater flooding, severely limits most park uses, unless expensive construction techniques are followed. On a number of VL tracts, particularly VL1, the flooding is accompanied by active sedimentation. Major construction activities (e.g. roads) on such tracts will change sedimentation and erosional patterns.

EACH TRACT SHOULD BE EVALUATED IN DETAIL FOR SPECIFIC PROPOSED USES.

WF - WILDFLOWER ECOSECOTION

The Wildflower (WF)Ecosection encompasses inclined landforms comprised of calcareous, medium textured colluvium in the Upper Subalpine portion of the Subalpine Ecoregion. Brunisolic and Regosolic soils dominate under avalanche complex v.t.s., Engelmann spruce-subalpine fir closed and open forest, mixed coniferous open forest, grassland, shrub thicket, and grassy tundra. Table 121 outlines five WF Ecosites separated primarily by vegetational differences.

Table 120. Wildlife features of the VL Ecosites

Ecosite	Ungulates		Carnivores		Small Mammals		Birds
	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
VL1	high	moose elk	medium	weasel wolf coyote	low	beaver meadow vole	very high
VL3	high	moose deer elk	high	wolf coyote weasel cougar lynx	high	snowshoe hare columbian ground squirrel red squirrel	high
VL4	high	moose elk deer	high	wolf coyote cougar lynx	high	dusky shrew snowshoe hare red squirrel deer mouse red-backed vole western jumping mouse	very high
VL5	high	moose elk	high	coyote wolf lynx cougar	high	masked shrew dusky shrew snowshoe hare red squirrel meadow vole	very high

Table 121. General features of the WF Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
WF1	Blanket, veneer over inclined bedrock	Colluvium C (calcareous, medium textured)	Eutric Brunisol, Regosol	Engelmann spruce - subalpine fir closed and open forest (C15, C21, O10)
WF2	Blanket, veneer over inclined bedrock, apron	Colluvium C (calcareous, medium textured	Eutric Brunisol, Regosol, Humic Regosol	Avalanche Complex 2 > Engelmann spruce - subalpine fir closed and open forest (C15, O10)
WF3	Blanket, veneer over inclined bedrock > inclined bedrock	Colluvium C (calcareous, medium textured	Eutric Brunisol, Regosol, Humic Regosol	Mixed coniferous open forest (O4) > Engelmann spruce - subalpine fir open forest (O10)
WF4	Blanket, veneer inclined bedrock	Colluvium C (calcareous, medium textured)	Eutric Brunisol, Regosol	Engelmann spruce forest (C33)
WF7	Blanket, veneer over inclined bedrock	Colluvium B & C (noncalcareous, medium textured)	Eutric & Melanic Brunisol, Humic Regosol	Grassland (H14), shrub thicket (S10), grassy tundra (H4)

WF occurs on or below steep valley walls and is associated with calcareous bedrock. Slopes generally range from 45 to 100%. Soils are rapidly to moderately well drained. Snow avalanching characteristically affects more than 50% of WF2. Unvegetated portions may constitute up to 50% of some WF2, WF3, and WF7 tracts. WF4 and WF7 occur primarily in the Front Ranges on dry, southerly aspets. WF3 is the steepest of the five WF Ecosites and has the greatest abundance of lithic soils and rock outcrops. Avalanche Complex 2, for WF2, is a heterogeneous complex of v.t.s. that includes subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (SI0), juniper-willow (L2), hairy wild rye-wild strawberry-fireweed (H5), fleabane-valerian (H16), plus intergrades, with S2 being most abundant.

WILDLIFE

Table 122. Wildlife features of the WF Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
WF1	low		low	marten	medium		low
WF2	high	mountain goat bighorn sheep caribou	medium	wolverine	low	pika columbian ground squirrel golden-mantled ground squirrel	low
WF3	high	mountain goat bighorn sheep	low		medium	yellow pine chipmunk deer mouse	low
WF4	high	bighorn sheep mountain goat elk deer	medium	cougar wolf coyote	low	snowshoe hare	low
WF7	very high	bighorn sheep mountain goat elk	low	cougar	high	heather vole meadow vole long-tailed vole pika columbian ground squirrel	low

The importance of WF Ecosites to wildlife is variable. All but WF1 are highly important to ungulates. All Ecosites are of low importance to birds. To carnivores and small mammals the Ecosection is of low to moderate importance. Critical goat and sheep habitat occurs on WF2, WF3, WF4 and WF7.

MANAGEMENT CONSIDERATIONS

Steep and locally unstable (colluviating) slopes are limiting for many park uses. Snow avalanching, whether local (on WF1, WF3, WF4) or extensive (WF2), will affect winter uses. Shallow soils and bedrock outcrops on WF3 are factors to consider when planning certain uses (e.g. trails). Vegetation of WF3 recovers slowly from disturbances. WF4 is of limited areal extent. It is expected that vegetation on WF4 and WF7

recovers slowly from disturbances and that vegetation removal will significantly increase the chances of erosion, particularly colluviation. Droughty conditions on WF4 and WF7 will compound potential revegetation problems.

WH - WHITEHORN ECOSECTION

The Whitehorn (WH) Ecosection encompasses inclined landforms comprised of noncalcareous, medium textured colluvium in the Upper Subalpine portion of the Subalpine Ecoregion. Dystric Brunisols dominate under avalanche complex v.t.s., subalpine larch-subalpine fir forest, Engelmann spruce-subalpine fir closed and open forest, and mixed coniferous open forest. Table 123 outlines four WH Ecosites separated primarily by vegetational differences. Landscape position is shown in Fig. 31.

Table 123. General features of the WH Ecosites

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
WH1	Blanket, veneer over inclined bedrock	Colluvium B (noncalcareous, medium textured)	Dystric & Sombric Brunisol	Subalpine larch-subalpine fir forest (C23)
WH2	Blanket, veneer over inclined bedrock	Colluvium B (noncalcareous, medium textured)	Dystric Brunisol	Engelmann spruce-subalpine fir closed and open forest (C15, O10, C21)
WH3	Blanket, veneer over inclined bedrock, apron	Colluvium B (noncalcareous, medium textured)	Dystric & Sombric Brunisol > Humic Regosol	Avalanche Complex 2 > Engelmann spruce-subalpine fir closed and open forest (C15, O10)
WH5	Blanket, veneer over inclined bedrock > inclined bedrock	Colluvium B (noncalcareous, medium textured)	Dystric Brunisol > Regosol	Mixed coniferous forest (O4) > Engelmann spruce - subalpine fir open forest (O10)

WH occurs on or below steep valley walls and is associated with Miette Group or noncalcareous Mesozoic strata. Surface veneers of Eolian material B (altered, medium textured) occur sporadically. Slopes commonly range from 45 to 100%. Soils are rapidly to moderately well drained. Occurrences of subalpine larch-subalpine fir forest (C23) are restricted to southern Banff. Snow avalanching affects more than 50% of WH3. Unvegetated portions may constitute up to 50% of WH3 and WH5 tracts. WH5 is the steepest of the four WH Ecosites and has the greatest abundance of lithic soils and rock outcrops. Avalanche Complex 2, for WH3, is a heterogeneous complex of v.t.s. that includes subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (S10), juniper-willow (L2), hairy wild rye-wild strawberry fireweed (H5), fleabane-valerian (H16), plus intergrades, with S2 being most abundant.

WILDLIFE

Overall, WH is of low importance to wildlife. However, avalanche slopes are highly important where they occur. Most areas are forested and receive deep snow which

Fig. 31 Landscape schematic of the Whitehorn (WH) Ecosite in relation to other Ecosites.

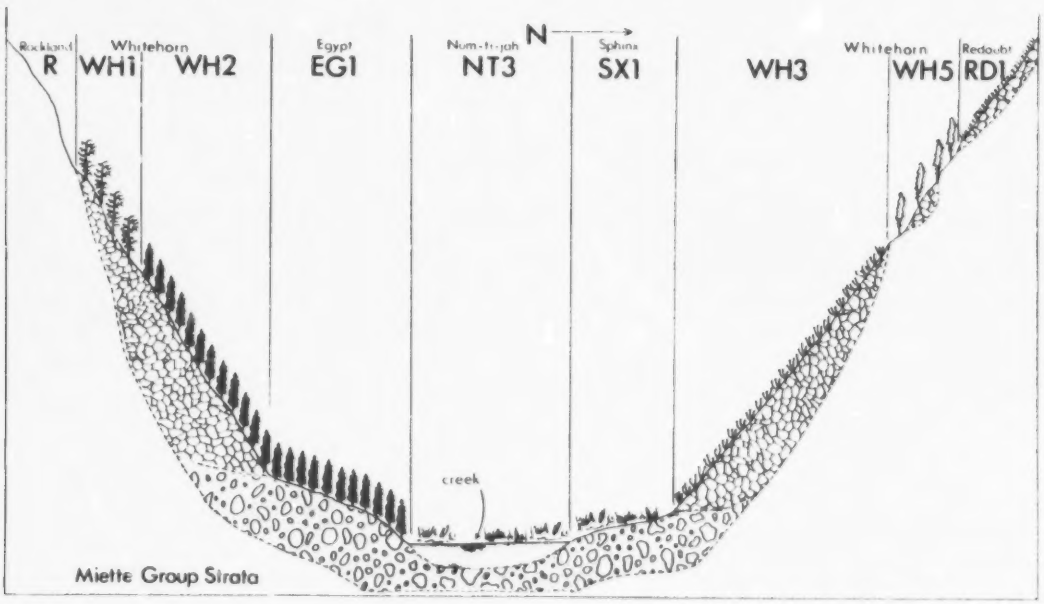

Table 124. Wildlife features of the WH Ecosites

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
WH1	low		low	marten	high	heather vole	low
WH2	high	elk	low		medium	pika	medium
WH3	low		low	marten	low	pika hoary marmot	low
WH5	low		low		low	dusky shrew heather vole pika hoary marmot columbian ground squirrel	high

limits the usefulness to large mammnals. Some small mammals reach high densities on some of the Ecosites.

MANAGEMENT CONSIDERATIONS

WH1 and WH2 are of limited areal extent. Steep and locally unstable (colluviating) slopes are limiting factors to be considered for many park uses. Snow avalanching, whether local (on WH1, WH2, WH5) or extensive (WH3), affects winter uses. The shallow soils and bedrock outcrops of WH5 are other factors to consider when planning some uses (e.g. trails). Vegetation on WH5 is expected to recover slowly from disturbances.

WW - WARWICK ECOSECTION

The Warwick (WW) Ecosection encompasses hummocky and ridged morainal landforms comprised of calcareous, medium textured till in the Lower Subalpine portion of the Subalpine Ecoregion. Regosolic soils are dominant under herb mat vegetation. Table 125 summarizes the WW1 Ecosite. WW1 is an uncommon Ecosite restricted to the Main Ranges near the Continental Divide and is associated with recently retreating glaciers.

Table 125. General features of the WW1 Ecosite

Ecosite	Surface Expression	Genetic Material Unit	Soils	Vegetation
WW1	Hummocky, ridged	Till C (calcareous, medium textured)	Regosol, Humic Regosol	Herb mat (H8)

WW1 tracts occur on valley bottoms and lower slopes. Ice Contact Stratified Drift B (calcareous, variably textured) is an accessory genetic material. Complex slopes range from 5 to 45%. Soils are moderately well drained and display incorporation of decomposing herb mat (H8) vegetation into the surface mineral horizon. The yellow dryad-willow herb v.t. is a community that pioneers neoglacial landscapes.

WILDLIFE

WW1 is of low importance to wildlife.

MANAGEMENT CONSIDERATIONS

WW1 is of limited areal extent. The dominant Regosolic soils indicate recent glacial deposition. Vegetation can probably withstand moderate use but once destroyed is expected to recover slowly. Of particular concern are steep slopes and imperfectly to poorly drained depressional localities. Areas of WW1 are ideal for research purposes in such fields as glacial geology and geomorphology, paleoclimatic studies, soil genesis, vegetational succession, and naturally disturbed site rehabilitation.

ECOSITE MODIFIERS

Ecosite Modifiers are applied to individual tracts which are not part of an Ecosite concept. The Ecosite Modifiers are listed below.

Table 126. Wildlife features of the WW1 Ecosite

	Ungulates		Carnivores		Small Mammals		Birds
Ecosite	Ranking	Important Species	Ranking	Important Species	Ranking	Important Species	
WW1	low		medium	marten weasel	low	golden-mantled ground squirrel deer mouse	low

A - AVALANCHED

The Ecosite Modifier **Avalanched** (A) is used with a map symbol when 20 to 50% of a tract is modified by frequent snow avalanches, an occurrence common to many Subalpine Ecosites. The avalanching has little direct effect on soils but is largely responsible for the following v.t.s: subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (S10), juniper-willow (L2), hairy wild rye-wild strawberry-fireweed (H5), fleabane-valerian (H16), and aspen/hairy wild rye-showy aster (C22).

MANAGEMENT CONSIDERATIONS

Ecosites affected by avalanching require modified management considerations, particularly for winter uses.

B - BURNED

The Ecosite Modifier **Burned** (B) is used when 50% or more of the vegetation of a tract is modified by fire and is not a recognized v.t.

MANAGEMENT CONSIDERATIONS

Burned areas may be conducive to accelerated rates of erosion, especially in the few years immediately following fire. They are often favorable for wildlife since fire usually results in forest being replaced by herbaceous or shrubby vegetation. Also, burned areas may serve as a research sites to determine the pathways and rates of vegetational succession.

F - FAILED

The Ecosite Modifier **Failed** (F) is of three types: old (inactive) rock glaciers; areas of slow mass movement, guided by a slip surface; and areas of deep, extensive and severe solifluction.

MANAGEMENT CONSIDERATIONS

Failed tracts with old rock glacier landforms should not receive changed management consideration because the rock glaciers are not expected to reactivate. Failed terrain that includes mass movement and severe solifluction will influence management considerations for park uses. Such tracts should be evaluated individually to determine the

potential for further slope failure.

X - LITHIC

The Ecosite Modifier **Lithic** (X) is used when $\geq$ 50% of a tract is modified by shallow soils over bedrock, where the lithic contact is within the normal depth of the soil control section.

MANAGEMENT CONSIDERATIONS

Shallow soils and bedrock will change management considerations for Lithic Ecosites. Uses that require deep unconsolidated material (e.g. sewage disposal) will be precluded.

MISCELLANEOUS LANDSCAPES

CL - COLLUVIAL LANDSLIDE

The Miscellaneous Landscape **Colluvial Landslide** (CL) encompasses areas of sparsely vegetated landslide materialls. Deposited by rapid gravity-induced movement, these deposits are a chaotic, generally loose, mixture of soil and rubble from a variety of genetic material sources. Surface expression is irregular, usually hummocky. Nonsoil dominates the landscape, with Regosolic soils occurring in local areas. CL is characterized by >80% unvegetated terrain. The remaining 20% is sparsely vegetated with saxicolous lichen (H12), spotted saxifrage-hairy wild rye (H20), and mountain avens-snow willow-moss campion (H1) v.t.s.

MANAGEMENT CONSIDERATIONS

Irregular topography, lack of soil and rubbly, blocky surfaces are the major factors to consider as limitations for most park uses.

CR - COLLUVIAL RUBBLE

The Miscellaneous Landscape **Colluvial Rubble** (CR) is derived from Colluvium A, B, or C, depending on the characteristics of the source bedrock. Colluvial Rubble is a subset of *colluvium* as defined by C.S.S.C. (1978b) which results from slow, gravity-induced movement caused by surface creep, solifluction, and sheet erosion. Nonsoil dominates, but Regosolic soils occur locally. CR tracts may be unvegetated, or sparsely vegetated with saxicolous lichen (H12) and mountain avens-snow willow-moss campion (H1) v.t.s.

MANAGEMENT CONSIDERATIONS

Land stability, as well as lack of soil and vegetation, are major factors limiting most recreational park uses. The colluviation process is slower than for CL and thus, may permit some uses, (e.g. trails) but at significant development and maintenance costs.

GL - GLACIER

The Miscellaneous Landscape **Glacier** (GL) includes glacier, firn, ice field, and glacierette. GL tracts occur in all Ecoregions except the Montane and occur mostly near the Continental Divide. GL is unvegetated and nonsoil. Occasionally GL is mapped as a complex with other Miscellaneous Landscapes.

MANAGEMENT CONSIDERATIONS

GL areas have scientific, ecological, and tourist interest. The implications for use are complex and require site specific studies by qualified personnel. The ecological concerns involve long term climatic and hydrologic influences of the environment.

M - RECENT MORAINE

The Miscellaneous Landscape **Recent Moraine** (M) encompasses areas of sparsely vegetated till, primarily Till C (calcareous, medium textured), and occurs in the Subalpine and Alpine Ecoregions near the Continental Divide. Ice retreat from these areas is so recent that Regosols and nonsoil are characteristic. The yellow dryad–willow herb (H8) v.t. usually pioneers these neoglacial landscapes. M is occasionally mapped as a complex with other Ecosites and Miscellaneous Landscapes.

MANAGEMENT CONSIDERATIONS

Areas of Recent Moraine have scientific, ecological, and tourist interest, particularly for geomorphological and pedological studies, as well as paleoecological studies of vegetational succession. The lack of soil and vegetation preclude many recreational park uses.

P - PITS

The Miscellaneous Landscape **Pits** (P) include borrow pits and fills, gravel pits, quarries, and refuse disposal sites. Because of small size, many disturbed sites cannot be mapped.

MANAGEMENT CONSIDERATIONS

Some Pits have been used as overflow campgrounds. These highly disturbed areas could often benefit from reclamation to blend them into the landscape more aesthetically and restore their biological productivity

R - ROCKLAND

The Miscellaneous Landscape **Rockland** (R) is comprised of consolidated bedrock of all lithologies and occurs in all Ecoregions. It is predominantly nonsoil and unvegetated, although some high elevation tracts are sparsely vegetated with saxicolous lichen (H12) and mountain avens–snow willow–moss campion (H1) v.t.s. Some tracts also have stunted trees growing in cracks and shallow pockets of soil. R is occasionally mapped as a complex with other Ecosites and Miscellaneous Landscapes.

MANAGEMENT CONSIDERATIONS

Lack of soil and vegetation preclude many recreational park uses. Steepness and safety problems are other limitations to their use. Aesthetic values are high, as is their use for geological studies.

RG - ROCK GLACIER

The Miscellaneous Landscape **Rock Glacier** (RG) includes predominantly unvegetated masses of poorly sorted, angular coarse fragments and fine earth material, cemented

by interstitial ice a meter or more below the surface. It is a product of colluvial and glacial processes. RG is dominantly nonsoil, although Regosols do occur on older stable portions where vegetation has become established. RG is often mapped as a complex with Talus (T).

MANAGEMENT CONSIDERATIONS

RG areas are of scientific, ecological, and tourist interest. Steepness and lack of soil and vegetation are severely limiting factors for most recreational park uses.

SC - RECENT STREAM CHANNEL

The Miscellaneous Landscape **Recent Stream Channel** (SC) consists of level floodplains comprised primarily of calcareous, coarse textured glaciofluvial material in all Ecoregions. SC originates from glacial meltwater streams which are usually still rapidly aggrading. It is characterized by Regosolic and Gleysolic soils associated with sparsely or unvegetated sites. Pioneering v.t.s.,such as sedge-saxifrage (H3), herb mat (H8) and willow/horsetail (S7), occur in small, isolated patches. SC may also be mapped as a complex with other fluvial landscapes.

MANAGEMENT CONSIDERATIONS

Wetness, continuing landform building processes and, in some instances, flood hazard, are severe limitations to most park uses. SC tracts are ideal for studying vegetational succession, as well as for pedogenic studies.

T - TALUS

The Miscellaneous Landscape **Talus** (T) encompasses areas of a loose, angular, coarse fragment phase of either Colluvium A, B, or C, depending on the source lithology. Talus is a subset of *colluvium* as defined by C.S.S.C. (1978b) formed by gravitational falling, rolling, and sliding of individual fragments dislodged by physical weathering of steep, resistant rock walls. Talus is dominantly nonsoil and unvegetated, although a few tracts have Regosolic soils associated with sparse vegetation. It occurs in all Ecoregions and is occasionally mapped with other Miscellaneous Landscapes.

MANAGEMENT CONSIDERATIONS

Steepness, instability, and lack of soil and vegetation result in severe limitations for most recreational park uses.

W - WATER BODIES

The Miscellaneous Landscape **Water Bodies** (W) include named and unnamed lakes and ponds, both natural and artificial. The smallest Water Bodies shown are approximately 25 ha and are delineated at the high water level where seasonal fluctuations are evident. Water Bodies are mapped in all Ecoregions.

MANAGEMENT CONSIDERATIONS

Water bodies should be inventoried individually.

CHAPTER IV - RESOURCE USE INTERPRETATION [2]

W.D. Holland

INTRODUCTION

The soil, vegetation, and wildlife of the National Parks are natural resources which are studied to provide information useful in making decisions, with the expectation of a profitable return, social benefit, or reduction in the cost of management. The study and mapping of ecological (biophysical) resources serves this practical purpose by accumulating technical information on the natural resources and by providing this information for use in the planning and management of specific land areas or kinds of soil, vegetation, or wildlife.

This involves:

1. resource inventory – gathering basic information on the kinds, amounts, and distribution of soil, vegetation, and wildlife.
2. resource use interpretation – developing an interpretive classification
3. resource management plans – applying the interpretive classification to specific land areas and resources, and developing management plans.
4. resource management – operational application of the management plans

The primary purpose of the Banff–Jasper Ecological Land Classification has been resource inventory, and the maps and volumes of this report provide the basic resource information. This chapter deals with interpretive classification. The activities in points 3 and 4 above are beyond the scope of this report.

INTERPRETIVE CLASSIFICATION

Basic resource inventories contain a wealth of information which managers often find overwhelming in volume and detail. Therefore, it is necessary to simplify the information by grouping resource components into interpretive classes for specific purposes (Montgomery and Edminster 1966, Bauer 1973, Pettry and Coleman 1973, Zayach 1973, Westerveld and van den Hurk 1973). Each class contains resource components which have similar suitabilities or responses for a particular use or management. Thus, several Ecosites which have a similar suitability for trail use would be grouped into the same interpretive class. A range of classes, from high to low suitability, is developed for each specific use. Often the factors limiting suitability are noted as subclasses. For example, flooding may cause a low interpretive class rating for a particular Ecosite, while the low rating of another is due to excessive stoniness. Interpretive classifications are use specific and an Ecosite or land area which is rated low for one use may be rated high for others. Consequently, managers will need a series of interpretive classifications, all founded on the basic resource inventory, to make decisions involving various uses or management practices.

---

[2] *Interpretation*, as used here, is the grouping of resource components on the basis of similar properties which affect their use. This is a different meaning of *interpretation* than often used by Parks Canada; this latter refers to the explanation of park features to visitors.

In making an interpretive classification, several principles should be observed:

1 Define clearly the purpose of each classification.

2 Classifications are generally based on the kinds and degree of limitation to a specific use. The ranges of the resource qualities which define the various classes should be defined as precisely as possible. Resource groupings are usually according to one resource quality.

3 Classifications generally contain few classes. An odd number of classes permits two extremes as well as a mean or average class, three to five being most common. More classes may be needed for intensive management, but a large number of classes becomes unwieldy and does little to help simplify the information.

4 The intensity of management for a particular classification must be stated because many limitations can be reduced by management. Thus, a factor, such as high tree density, which may be severely limiting in a backcountry campsite with a low intensity of management may present less severe limitations in a highly developed area where more in time management permits clearing of access roads, paths, and tent pads.

5 Interpretive classes are relative – good, fair, poor. Such groupings are dynamic and can be changed as situations change; for example, an altered management practice.

Examples of these principles applied to interpretive classifications based on soil limitations (Table 127) are in *Soils of Waterton Lakes National Park* (Coen and Holland 1976).

Table 127 Example interpretations of soil characteristics for selected park uses (Coen and Holland 1976)

Map Units	Degree and Nature of Limitations for Recreation Uses						Degree and Nature of Limitations for Engineering Uses						Susceptibility to water erosion
	Playgrounds		Camp Areas		Paths & Trails		Septic Tank Fields			Bldgs with Basements		Local Roads	
	slight	moder- severe ate	slight	moder- severe ate	slight	moder- severe ate	slight	moder- severe ate	pollution hazard	slight	moder- severe ate	slight	moder- severe ate
2 2 AC,AD	Stony	Slope CF[1] Moist		CF Moist Stony		CF Stony	nil		Fo		Stony	Stony		Low
1 1 DF,FF, 1 F	Stony	Slope CF Moist		Slope Moist Stony CF		Slope Stony CF		Slope	Fo		Stony Slope		Slope	Low
1 1 F,C, 1 DE	Stony	Slope CF Moist		Stony Slope CF Moist		Stony Slope CF		Stony Slope	Fo		Stony Slope		Slope	Moderate
15 AB	Flood Wet			Flood		Flood		W.T Flood			Wet W.T. Str Flood		Flood Frost Str	Low
17 17 AC,AD		Moist CF		CF Moist	nil		nil		Fo	nil		nil		Low
21 AC		CF Moist		CF Moist		CF	nil		Fo	Stony		Stony		Moderate
21 F		CF Moist		CF Moist Slope		Slope CF		Slope	Fo		Slope		Slope	High
91 AB		wet Flood		Wet Flood		Wet Flood	Perm	W.T. Flood			Sh-Sw Wet, Str W.T. Frost Flood		Sh-Sw Wet Frost Flood Str	Low

[1] Abbreviations as follows: CF = Coarse fragments, Stony = Surface stoniness, Moist = Useful moisture; Slope = % slope; Fo = Pollution hazard; Flood = Flooding, Wet = Wetness (soil drainage); W.T. = Depth to seasonal water table, Str = Strength of soil as rated by Unified or AASHO; Frost = Susceptibility to frost heave, Perm = Permeability, Sh-Sw = Shrink-swell potential

Much of the interpretive information in the *Management Considerations* section of the Ecosection descriptions in this volume is based on soils. Procedures similar to those in Table 127 can be applied to vegetation and wildlife information as well. Much of the interpretive classification of soils is based on physical characteristics which have been well investigated by engineering research. However, comparatively little research has been done on the response of vegetation and wildlife to various uses and intensities of management. Thus, making realistic predictions of responses for all Ecosites is not possible within the framework of this study. Lacking such information, it is possible to make only limited interpretations based on the response of Ecosites

which are currently receiving certain types and intensities of use. For example, if an area of a certain Ecosite is being used as a campsite and is deteriorating, one can assume that other areas of the Ecosite which receive the same type and intensity of use and management would also deteriorate. Such a limited interpretation would not apply to any other than this specific Ecosite.

Interpretive classifications may be presented either as tables (Coen and Holland 1976) or maps (Lindsay et al. 1973) in which areas with similar capability and limitation are designated with a common symbol. The single factor maps prepared by Kurt Seel of Parks Canada, Western Region, Calgary, are examples of interpretations that are effective for planning because the maps are easily understood.

Interpretive classifications also have limitations:

1. It is assumed that enough is known about the effects on a resource component of a certain use or management practice to accurately assess suitability. Such information is rarely as complete as desired. Thus, interpretive classifications are always subject to revision as new knowledge becomes available.
2. The boundaries on interpretive maps do not separate resource components or Ecosites *per se*, but are based on resource characteristics which significantly affect the specific use being examined.
3. An interpretive classification can be used only for the specific use for which it was developed. If information on another use is needed, a new grouping must be derived using the basic resource information.
4. The person developing an interpretive classification must be aware of the limitations of the basic resource inventory information. It is relatively easy to go beyond that range of validity of the data. Scale, in particular, must be carefully considered. Resource information in this report is presented at a scale of 1:50,000. Many land management decisions will require site specific investigation to determine if the broader scale interpretive class based on an Ecosite in this report is appropriate for a smaller specific area.

Four sources of information for an interpretive classification are:

1. Field data gathered during the inventory stage to describe classify, and quantify natural resources such as landforms, soils, vegetation, and wildlife.
2. Research plot studies testing the response of key soils, vegetation types or wildlife habitats to various management practices, e.g. irrigation, fertilizing, planting, cutting or burning.
3. Indirect evaluations estimating use suitability of unknown resources by comparing them with those for which information is available.
4. User experience utilized to determine the nature and degree of resource use suitability or limitation of tracts known to represent a particular Ecosite concept. Especially helpful experience may be that of wardens, naturalists or other personnel with extensive experience in National Parks.

Information about an Ecosite, derived from one or more of these four sources, can then be used to develop predictions about the response of other tracts mapped as that Ecosite to the use under consideration.

Generally, application of the predictions involves three steps:

1. All the natural resources are listed. This will usually be a listing of all the map symbols which represent unique tracts of land.
2. All data describing the natural resources are assembled. Items frequently affecting parks use often include, for example, slope, aspect, elevation, vegetation type, snow depth, and various aspects of wildlife use.
3. Using the principles identified above, the data are grouped into classes based on the information associated with each map symbol listed in 1 above. A five class rating might be:
   - G = Good (slight limitations)
   - F = Fair (moderate limitations)
   - P = Poor (severe limitations)
   - V = Very Poor (very severe limitations)

U = Unsuitable

The following demonstrates the interpretive classification process. In this example, the objective is to locate campground sites that can accomodate 2,000 people per night. The selection criteria for large campgrounds first must be established and then the land inventory data searched. Selection criteria might include:

1. Snow avalanche risk
2. Flooding hazard
3. Slope of the landform
4. Soil attributes which affect revegetaion, dustiness or ease of foot travel
5. V.t.s that affect ground cover, shade, screening, resistance to use or rapid recovery after use.
6. Wildlife attributes, such as use for winter range, calving, denning, nesting or migration
7. Size limits which affect use of the tract
8. Compatability with adjacent land uses.

The nature and degree of the limitation, as judged by the above selection criteria, determines to which of the five classes (Good to Unsuitable) a tract will be assigned. The guidelines established here should be carefully recorded so that as knowledge improves, the class limits can be reassessed.

Land classification maps and accompanying information can be stored by computers. Programs are being developed to allow planning teams to alter guidelines and then assess the effect of this alteration on the class limits of interpretive maps. This approach allows the development of a set of scenarios representing several proposed management or design alternatives.

There is no best way to interpret basic ecological inventory data. The foregoing outlines several principles and an example of one appraoch to analyzing inventory data. The method chosen however, must recognize the spatial limitations of the data and the reliability limits of the analytical data about Ecosites upon which responses are predicted.

LIST OF FIGURES

1. Location of study area.
2. Mean monthly temperature and precipitation for Banff and Jasper townsites and Village Lake Louise.
3. Classification of Banff and Jasper townsites and Village Lake Louise climates according to Köppen.
4. Geologic subprovinces of Banff and Jasper.
5. Hydrographs showing dominance of summer flows for streams in Banff and Jasper National Parks (from data supplied by Water Survey of Canada).
6. Drainage systems of Banff and Jasper National Parks.
7. Generalized time scale and stratigraphic column for Banff and Jasper.
8. Textural variation among selected C horizons sampled on landslide material.
9. Textural variation among selected Bm, BC, and C horizon samples of noncalcareous, coarse textured colluvium (Colluvium A).
10. Textural variation among selected Bm, BC, and C horizon samples of noncalcareous, medium textured colluvium (Colluvium B).
11. Textural variation among selected BC and C horizon samples of calcareous, medium textured colluvium (Colluvium C).
12. Textural variation of selected BC and C horizon samples of coarse textured, noncalcareous till (Till A).
13. Textural variation of selected BC and C horizon samples of medium textured, noncalcareous till (Till B).
14. Textural variation of selected C horizon samples of calcareous, medium textured till (Till C).
15. Textural variation among selected C horizons of all pedons sampled on calcareous, coarse textured glaciofluvial material (Glaciofluvial material B).
16. Textural variation among selected A, B, and C horizon samples of altered, fine textured, stratified fluviolacustrine material (Fluviolacustrine material A).
17. Textural variation among selected A and C horizon samples of calcareous, fine textured, stratified fluviolacustrine material (Fluviolacustrine material B).
18. Textural variation among selected BC and C horizon samples of calcareous, fine textured glaciolacustrine material.
19. Textural variation among selected A, B, and C horizon samples of calcareous, medium textured eolian material (Eolian material A).
20. Textural variation among selected A, B, and C horizon samples of altered, medium textured eolian material (Eolian material B).
21. Ecoregions of Banff and Jasper.
22. Elevation ranges of Ecoregions and Ecoregion subunits in Banff and Jasper National Parks.
23. Some plant succession trends evident in Banff and Jasper National Parks.
24. Location of features not on the National Topographic Series maps.
25. Distribution of *Hippuris montana* in Banff and Jasper.
26. Distribution of *Sedum divergens* in Banff and Jasper.
27. Distribution of *Tsuga heterophylla* in Banff and Jasper.
28. Distribution of *Vaccinium ovalifolium* in Banff and Jasper.
29. Legend identifying components of the schematic cross-section diagrams illustrating the Ecosite descriptions.
30. Landscape schematic showing relative positions of the Azure 1 (AZ1) and Topaz 1 (TZ1) Ecosites to other Ecosites.
31. Landscape schematic showing relative positions of the Baker Creek (BK) Ecosites and a few other Lower Subalpine Ecosites.
32. Landscape schematic showing the relationship of the Boulder Pass (BP) Ecosites to other Ecosites.
33. Landscape schematic showing the relationship of the Bow Valley (BV) Ecosites to other Ecosites.
34. Landscape schematic showing the relationship of the Bryant (BY) Ecosite to other Ecosites.
35. Landscape schematic showing the relationship of the Cavell (CA) Ecosites to other Ecosites.
36. Landscape schematic showing the relationship of the Copper 1 (CP1) Ecosite to other Ecosites.
37. Landscape schematic showing the relationship of the Consolation Valley 1 (CV1) Ecosite to other Ecosites.
38. Landscape schematic showing the relationship of the Devona 1 (DV1) Ecosite to other Ecosites.
39. Landscape schematic showing the relationship of the Egypt (EG) Ecosites to other Ecosites.
40. Landscape schematic showing the relationship of the Endless Chain Ecosites (EN1, EN2, and EN3) to other Ecosites.
41. Landscape schematic showing the relationship of the Goat (GT1, GT2) Ecosites to other Ecosites.
42. Landscape schematic showing the relationship of the Katherine 1 (KA1) Ecosite to other Ecosites.
43. Landscape schematic showing the relationship of the Larch Valley (LV) Ecosites to other Ecosites.
44. Landscape schematic showing the relationship of the Merlin Castle 1 (MC1) Ecosite to other Ecosites.

45. Landscape schematic of the Nigel 1 (NG1) Ecosite.
46. Landscape schematic showing the relationship of the Nashan 1 (NH1) Ecosite to other Ecosites.
47. Landscape schematic showing the relationship of the Norquay (NY) Ecosites to other Ecosites.
48. Landscape schematic showing the relationship of the Peyto Lake (PL) Ecosites to other Ecosites.
49. Landscape schematic showing the relationship of Panorama Ridge (PR) Ecosites to other Ecosites.
50. Landscape schematic showing the relationship of Patricia (PT) Ecosites to other Ecosites.
51. Landscape schematic showing the relationship of the Sawback (SB1, SB2) Ecosites to other Ecosites.
52. Landscape schematic showing the Snowflake 1 (SF1) Ecosite in relation to other Ecosites.
53. Landscape schematic showing the relationship of the Tyrrell (TR) Ecosites to other Ecosites.
54. Landscape schematic showing the relationship of the Whitehorn (WH) Ecosites to other Ecosites.
55. Landscape schematic showing the relationship of the Warwick 1 (WW1) Ecosite to other Ecosites.

LIST OF TABLES

1. Mean monthly temperature and precipitation at Banff and Jasper townsites and Village Lake Louise.
2. Average annual precipitation, October 1966 to September 1980, for stations in Jasper National Park.
3. Average annual precipitation, October 1966 to September 1980, for stations in Banff National Park.
4. Comparison of short term (October 1966 - September 1980) with long term (1941 - 1970, Environment Canada, 1975) precipitation data at Banff and Jasper townsites and Village Lake Louise.
5. Correlation of generalized bedrock lithology with calcareousness and textural groups of unsorted genetic materials.
6. Characteristics of modal unconsolidated mineral genetic materials within Banff and Jasper.
7. Ecological moisture regime classes (Walmsley et al. 1980).
8. Stands representing the Douglas fir/hairy wild rye (C1) v.t.
9. Stands representing the white spruce/fern moss (C2) v.t.
10. A comparison of four *Picea glauca* v.t.s. showing dominant species by layer.
11. Stands representing the lodgepole pine/juniper/bearberry (C3) v.t.
12. A comparison of five *Pinus contorta* v.t.s.
13. Stands representing the white spruce/prickly rose/horsetail (C4) v.t.
14. Stands representing the white spruce-Douglas fir/feathermoss (C5) v.t.
15. Stands representing the lodgepole pine/buffaloberry/showy aster (C6) v.t.
16. Stands representing the black spruce-lodgepole pine/willow/sedge (C8) v.t.
17. Stands representing the lodgepole pine/dwarf bilberry (C9) v.t.
18. Stands representing the lodgepole pine/green alder/feathermoss (C10) v.t.
19. Stands representing the lodgepole pine/feathermoss (C11) v.t.
20. Stands representing the Engelmann spruce-whitebark pine/false azalea (C12) v.t.
21. Stands representing the Engelmann spruce-subalpine fir/feathermoss (C13) v.t.
22. Stands representing the Engelmann spruce-subalpine fir/false azalea (C14) v.t.
23. Stands representing the Engelmann spruce-subalpine fir/grouseberry (C15) v.t.
24. Stands representing the aspen/hairy wild rye-peavine (C16) v.t.
25. Stands representing the balsam poplar/buffaloberry (C17) v.t.
26. Stands representing the lodgepole pine/buffaloberry/grouseberry (C18) v.t.
27. Stands representing the lodgepole pine/buffaloberry/twinflower (C19) v.t.
28. Stands representing the lodgepole pine/false azalea/grouseberry (C20) v.t.
29. Stands representing the Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.
30. Stands representing the aspen/hairy wild rye-showy aster (C22) v.t.
31. Stands representing the subalpine larch-subalpine fir/grouseberry- everlasting (C23) v.t.
32. Stands representing the Engelmann spruce-subalpine fir/rock willow/white mountain heather (C24) v.t.
33. Stands representing the white spruce/buffaloberry/fern moss (C26) v.t.
34. Stands representing the white spruce/prickly rose/fern moss (C27) v.t.
35. Stands representing the balsam poplar/horsetail (C28) v.t.
36. Stands representing the lodgepole pine/Labrador tea (C29) v.t.
37. Stands representing the Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.
38. Stands representing the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.
39. Stands representing the Engelmann spruce/horsetail/feathermoss (C32) v.t.
40. Stands representing the Engelmann spruce/hairy wild rye (C33) v.t.
41. Stands representing the Engelmann spruce-subalpine fir/heather/feathermoss (C34) v.t.
42. Stands representing the lodgepole pine-(Engelmann spruce)/crowberry/lichen (C35) v.t.
43. Stands representing the lodgepole pine-white spruce/willow/hairy wild rye (C36) v.t.
44. Stands representing the white spruce/buffaloberry/feathermoss (C37) v.t.
45. Stands representing the limber pine-Douglas fir/juniper/bearberry (O2) v.t.
46. Stands representing the white spruce/shrubby cinquefoil/bearberry (O3) v.t.
47. Stands representing the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) v.t.
48. Stands representing the Douglas fir/juniper/bearberry (O5) v.t.
49. Stands representing the Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6) v.t.
50. Stands representing the spruce/arrowgrass-sedge (O7) v.t.
51. Stands representing thef Engelmann spruce-subalpine fir/valerian-fleabane (O9) v.t.
52. Stands representing the Engelmann spruce-subalpine fir/heather (O10) v.t.
53. Stands representing the spruce/Labrador tea/brown moss (O11) v.t.

54. Stands representing the Engelmann spruce-subalpine fir/rock willow/alpine bearberry (O12) v.t.
55. Stands representing the Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) v.t.
56. Stands representing the paper birch/bearberry (O16) v.t.
57. Stands representing the white spruce/juniper/bearberry (O17) v.t.
58. Stands representing the Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) v.t.
59. Stands representing the Engelmann spruce-subalpine fir/mountain avens (O19) v.t.
60. Stands representing the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) v.t.
61. Stands representing the subalpine fir-willow (S2) v.t.
62. Stands representing the dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.
63. Stands representing the willow-dwarf birch/fleabane (S4) v.t.
64. Stands representing the willow-green alder/bluebell (S6) v.t.
65. Stands representing the willow/horsetail (S7) v.t.
66. Stands representing the willow/cinquefoil (S8) v.t.
67. Stands representing the dwarf birch-willow/kobresia (S9) v.t.
68. Stands representing the willow-dwarf birch-shrubby cinquefoil (S10) v.t.
69. Stands representing the willow/timber oatgrass (S11) v.t.
70. Stands representing the willow/hairy wild rye (S12) v.t.
71. Stands representing the shrubby cinquefoil/bearberry/northern bedstraw (L1) v.t.
72. Stands representing the juniper-willow (L2) v.t.
73. Stands representing the white mountain heather-mountain avens-snow willow (L4) v.t.
74. Stands representing the heather-everlasting (L5) v.t.
75. Stands representing the creeping juniper-wheatgrass-sedge (L6) v.t.
76. Stands representing the arctic willow-cinquefoil (L7) v.t.
77. Stands representing the mountain avens-snow willow-moss campion (H1) v.t.
78. Stands representing the black alpine sedge-everlasting (H2) v.t.
79. Stands representing the sedge-saxifrage (H3) v.t.
80. Stands representing the mountain avens-kobresia-bearberry (H4) v.t.
81. A stand representing the hairy wild rye-wild strawberry-fireweed (H5) v.t.
82. Stands representing the junegrass-pasture sage-wild blue flax (H6) v.t.
83. Stands representing the wheatgrass-pasture sage (H7) v.t.
84. Stands representing the yellow dryad-willowherb (H8) v.t.
85. Stands representing the mountain marigold-globeflower (H9) v.t.
86. Stands representing the cottongrass/moss (H10) v.t.
87. Stands representing the water sedge-beaked sedge (H11) v.t.
88. Stands representing the saxicolous lichen (H12) v.t.
89. Stands representing the Richardson needlegrass-junegrass-everlasting (H13) v.t.
90. Stands representing the hairy wild rye-junegrass-bearberry (H14) v.t.
91. Stands representing the mountain avens-curly sedge (H15) v.t.
92. Stands representing the fleabane-valerian (H16) v.t.
93. Stands representing the bluebunch wheatgrass-hairy wild rye-showy aster (H19) v.t.
94. Stands representing the spotted saxifrage-hairy wild rye (H20) v.t.
95. Organization of Ecosections by Ecoregion and genetic material classes.
96. Example of further Ecosection separations (refer to Table 95) within glacial genetic materials in the Lower Subalpine Ecoregion.
97. Example of Ecosite separations within an Ecosection.
98. General features of the Altrude (AL) Ecosites.
99. Pedon (Alberta 1974 No. 105) description of an Orthic Eutric Brunisol of the AL1 Ecosite.
100. Stand (AW5009) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the AL1 Ecosite.
101. Pedon (Alberta 1978 No. 216) description of an Orthic Eutric Brunisol of the AL2 Ecosite.
102. Stand (JC8081) illustrating the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. of the AL2 Ecosite.
103. General features of the Athabasca (AT) Ecosites.
104. Pedon (Alberta 1977 No. 132) description of an Eluviated Eutric Brunisol of the AT1 Ecosite.
105. Stand (JD7114) illustrating the lodgepole pine/juniper/bearberry (C3) v.t. of the AT1 Ecosite.
106. Pedon (Alberta 1976 No. 70) description of an overblown phase of an Orthic Melanic Brunisol representing soil of the AT3 Ecosite.
107. Stand (IC5003) illustrating the junegrass-pasture sage-wild blue flax (H6) v.t. of the AT3 Ecosite.
108. General features of the Azure 1 (AZ1) Ecosite.

109. Pedon (Alberta 1979 No. 38) description of an Eluviated Dystric Brunisol of dry upland segments of the AZ1 Ecosite.
110. Stand (JE9043) illustrating the Engelmann spruce-subalpine fir/heather (O10) v.t. of dry upland segments of the AZ1 Ecosite.
111. General features of the Baker Creek (BK) Ecosites.
112. Pedon (Alberta 1975 No. 350) description of Brunisolic Gray Luvisol of dry upland segments of the BK1 Ecosite.
113. Pedon (Alberta 1978 No. 22) description of a Rego Gleysol in wet depressional segments of the BK1 Ecosite.
114. Stand (JD6094) illustrating the lodgepole pine/buffaloberry/grouseberry (C18) v.t. of dry upland segments of the BK1 Ecosite.
115. Stand (IC8095) illustrating the spruce/Labrador tea/brown moss (O11) v.t. of wet depressional segments of the BK1 Ecosite.
116. Pedon (Alberta 1979 No. 94) description of an Eluviated Eutric Brunisol of dry upland segments of the BK4 Ecosite.
117. Stand (JE8021) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of dry upland segments of the BK4 Ecosite.
118. Stand (PA7016) illustrating the dwarf birch-shrubby cinquefoil/needlerush (S3) v.t. of wet depressional segments of the BK4 Ecosite.
119. Stand (PA8109) illustrating the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) v.t. of wet depressional segments of the BK6 Ecosite.
120. General features of the Boulder Pass (BP) Ecosites.
121. Pedon (Alberta 1979 No. 20) description of an Orthic Eutric Brunisol of the BP1 Ecosite.
122. Stand (JE9164) illustrating the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) v.t. of the BP1 Ecosite.
123. Pedon (Alberta 1978 No. 36) description of an Eluviated Eutric Brunisol of the BP2 Ecosite.
124. Stand (JE8151) illustrating the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. of the BP2 Ecosite.
125. General features of the Bow Summit (BS1) Ecosite.
126. Pedon (Alberta 1978 No. 25) description of an Orthic Melanic Brunisol of the BS1 Ecosite.
127. Stand (JC6025) illustrating the mountain avens-snow willow-moss campion (H1) v.t. of the BS1 Ecosite.
128. General features of the Bow Valley (BV) Ecosites.
129. Pedon (Alberta 1976 No. 63) description of an Eluviated Eutric Brunisol of the BV1 Ecosite.
130. Stand (LC9180) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the BV1 Ecosite.
131. Pedon (Alberta 1975 No. 107) description of an Eluviated Eutric Brunisol of the BV2 Ecosite.
132. Stand (AW5177) illustrating the lodgepole pine/false azalea/grouseberry (C20) v.t. of the BV2 Ecosite.
133. Stand (IC6100) illustrating the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. of the BV3 Ecosite.
134. General features of the Bryant (BY) Ecosites.
135. Pedon (Alberta 1978 No. 38) description of an Eluviated Eutric Brunisol of the BY1 Ecosite.
136. Stand (JD7021) illustrating the Engelmann spruce-subalpine fir/false azalea (C14) v.t. of the BY1 Ecosite.
137. Pedon (Alberta 1979 No. 91) description of an Orthic Eutric Brunisol of the BY2 Ecosite.
138. Stand (JD9082) illustrating the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t. of the BY2 Ecosite.
139. Pedon (Alberta 1978 No. 81) description of an Orthic Eutric Brunisol of the BY4 Ecosite.
140. Stand (AW7085) illustrating the Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t. of the BY4 Ecosite.
141. General features of the Brazeau (BZ) Ecosites.
142. Pedon (Alberta 1977 No. 118) description of an Eluviated Dystric Brunisol of the BZ1 Ecosite.
143. Stand (CC6068) illustrating the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t. of the BZ1 Ecosite.
144. Stand (JC7103) illustrating the lodgepole pine/Labrador tea (C29) v.t. of the BZ2 Ecosite.
145. General features of the Cavell (CA) Ecosites.
146. Pedon (Alberta 1977 No. 143) description of gleyed Podzolic soil of wet segments of the CA1 Ecosite.
147. Stand (AW5017) illustrating the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) v.t. of wet segments of the CA1 Ecosite.
148. Pedon (Alberta 1979 No. 78) description of an Eluviated Dystric Brunisol of the CA2 Ecosite.
149. Stand (JE9180) illustrating the Engelmann spruce-subalpine fir/false azalea (C14) v.t. of the CA2 Ecosite.
150. Pedon (Alberta 1979 No. 34) description of an Eluviated Dystric Brunisol of the CA4 Ecosite.
151. Stand (JD9030) illustrating the lodgepole pine/false azalea/grouseberry (C20) v.t. of the CA4 Ecosite.
152. General features of the Cyclone 1 (CN1) Ecosite.
153. Pedon (Alberta 1978 No. 51) description of a Cumulic Regosol of the CN1 Ecosite.

154. Stand (JC8076) illustrating the willow/hairy wild rye (S12) v.t. of the CN1 Ecosite.
155. General features of the Copper 1 (CP1) Ecosite.
156. Pedon (Alberta 1977 No. 139) description of an Orthic Dystric Brunisol of the CP1 Ecosite.
157. Stand (PA7185) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the CP1 Ecosite.
158. General features of the Consolation Valley 1 (CV1) Ecosite.
159. Pedon (Alberta 1975 No. 110) description of a Terric Mesisol of wet segments of the CV1 Ecosite.
160. Pedon (Alberta 1977 No. 115) description of a Rego Gleysol of wet segments of the CV1 Ecosite.
161. Stand (KS5091) illustrating the Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) v.t. of wet segments of the CV1 Ecosite.
162. General features of the Devona (DV) Ecosites.
163. Pedon (Alberta 1976 No. 66) description of an Orthic Regosol of the DV1 Ecosite.
164. Stand (JC7037) illustrating the creeping juniper-wheatgrass-sedge (L6) v.t. of the DV1 Ecosite.
165. Pedon (Alberta 1978 No. 17) description of a Cumulic Regosol of the DV2 Ecosite.
166. Stand (JM8001) illustrating the white spruce/prickly rose/fern moss (C27) v.t. of the DV2 Ecosite.
167. General features of the Eiffel 1 (EF1) Ecosite.
168. Pedon (Alberta 1979 No. 48) description of an Orthic Ferro-Humic Podzol of the EF1 Ecosite.
169. Stand (PA9129) illustrating the heather-everlasting (L5) v.t. of the EF1 Ecosite.
170. General features of the Egypt (EG) Ecosites.
171. Pedon (Alberta 1976 No. 98) description of an Orthic Dystric Brunisol of the EG1 Ecosite.
172. Stand (AW6092) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the EG1 Ecosite.
173. Pedon (Alberta 1977 No. 137) description of an Orthic Humo-Ferric Podzol of the EG2 Ecosite.
174. Stand (JD6086) illustrating the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. of the EG2 Ecosite.
175. Pedon (Alberta 1978 No. 41) description of an Orthic Dystric Brunisol of the EG4 Ecosite.
176. Stand (JE8159) illustrating the heather-everlasting (L5) portion of the v.t. pattern of the EG4 Ecosite.
177. General features of the Endless Chain (EN) Ecosites.
178. Pedon (Alberta 1978 No. 80) description of an Eluviated Dystric Brunisol of the EN1 Ecosite.
179. Stand (JC8095) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the EN1 Ecosite.
180. Pedon (Alberta 1979 No. 71) description of an Eluviated Dystric Brunisol of the EN2 Ecosite.
181. Stand (LC9171) illustrating the subalpine fir-willow (S2) v.t. of the EN2 Ecosite.
182. Pedon (Alberta 1978 No. 59) description of an Eluviated Dystric Brunisol of the EN3 Ecosite.
183. Stand (PA8157) illustrating the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) v.t. of the EN3 Ecosite.
184. General features of the Fireside 1 (FR1) Ecosite.
185. Pedon (Alberta 1978 No. 89) description of an Orthic Eutric Brunisol of the FR1 Ecosite.
186. Stand (JD8003) illustrating the lodgepole pine/buffaloberry/showy aster (C6) v.t. of the FR1 Ecosite.
187. General features of the Fairview (FV) Ecosites.
188. Pedon (Alberta 1978 No. 70) description of an Eluviated Dystric Brunisol of the FV1 Ecosite.
189. Stand (DJ8001) illustrating the subalpine fir-willow (S2) v.t. of the FV1 Ecosite.
190. Pedon (Alberta 1978 No. 83) description of an Eluviated Dystric Brunisol of the FV2 Ecosite.
191. Stand (JE8165) illustrating the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. of the FV2 Ecosite.
192. General features of the Garonne 1 (GA1) Ecosite.
193. Pedon (Alberta 1978 No. 65) description of Orthic Eutric Brunisols of the GA1 Ecosite.
194. Stand (JE8004) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the GA1 Ecosite.
195. General features of the Goat (GT) Ecosites.
196. Pedon (Alberta 1979 No. 68) illustrating Orthic Regosols of the GT1 Ecosite.
197. Stand (LC9183) illustrating an open variant of the lodgepole pine/juniper/bearberry (C3) v.t. of the GT1 Ecosite.
198. Pedon (Alberta 1979 No. 84) description of an Orthic Humic Regosol of southerly aspect segments of the GT2 Ecosite.
199. Stand (JD9075) illustrating the shrubby cinquefoil/bearberry-northern bedstraw (L1) v.t. of southerly aspect segments of the GT2 Ecosite.
200. General features of the Hector (HC) Ecosites.
201. Pedon (Alberta 1978 No. 68) description of a Rego Gleysol of the HC1 Ecosite.
202. Stand (JE8133) illustrating the Engelmann spruce/horsetail/feathermoss (C32) v.t. of the HC1 Ecosite.
203. Pedon (Alberta 1978 No. 90) description of a Rego Gleysol of the HC2 Ecosite.
204. Stand (JD7051) illustrating a bryoid-poor phase of the water sedge-beaked sedge (H11) v.t. of the HC2 Ecosite.
205. Pedon (Alberta 1979 No. 44) description of a Rego Gleysol of the HC4 Ecosite.

206. Pedon (Alberta 1979 No. 36) description of a Terric Mesisol of the HC4 Ecosite.
207. Stand (PA9124) illustrating the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) v.t. of the HC4 Ecosite.
208. Stand (LC9162) illustrating the dwarf birch-shrubby cinquefoil/needlerush (S3) v.t. of the HC4 Ecosite.
209. General features of the Hillsdale (HD) Ecosites.
210. Pedon (Alberta 1977 No. 138) description of a Cumulic Regosol of the HD1 Ecosite.
211. Stand (PA7175) illustrating the aspen/hairy wild rye-peavine (C16) v.t. of the HD1 Ecosite.
212. Pedon (Alberta 1978 No. 18) description of a Cumulic Regosol of the HD2 Ecosite.
213. Stand (SJ8003) illustrating the white spruce/shrubby cinquefoil/bearberry (O3) v.t. of the HD2 Ecosite.
214. Pedon (Alberta 1978 No. 99) description of a Cumulic Regosol of the HD3 Ecosite.
215. Stand (PA8165) illustrating the white spruce-Douglas fir/feathermoss (C5) v.t. of the HD3 Ecosite.
216. Pedon (Alberta 1975 No. 115) description of a Cumulic Regosol of the HD4 Ecosite.
217. Stand (IC5010) illustrating the june grass-pasture sage-wild blue flax (H6) v.t. of the HD4 Ecosite.
218. General features of the Heather (HE) Ecosites.
219. Pedon (Alberta 1977 No. 129) description of an Orthic Dystric Brunisol, lithic and turbic phase, of the HE1 Ecosite.
220. Stand (PA7119) illustrating white mountain heather-mountain avens-snow willow, (L4), an accessory v.t. of the HE1 Ecosite.
221. Pedon (Alberta 1976 No. 999) description of an Orthic Regosol, lithic phase, of the HE2 Ecosite.
222. Stand (JC6051) illustrating the mountain avens-snow willow-moss campion (H1) v.t. on vegetated portions of the HE2 Ecosite.
223. General features of the Ishbel (IB) Ecosites.
224. Pedon (Alberta 1979 No. 70) description of an Eluviated Eutric Brunisol of the IB1 Ecosite.
225. Stand (LC9186) illustrating the lodgepole pine/buffaloberry/grouseberry (C18) v.t. of the IB1 Ecosite.
226. Pedon (Alberta 1978 No. 49) description of an Orthic Regosol of the IB2 Ecosite.
227. Stand (SJ9123) illustrating the white spruce/juniper/bearberry (O17) v.t. of the IB2 Ecosite.
228. Pedon (Alberta 1978 No. 26) description of an Eluviated Eutric Brunisol of the IB3 Ecosite.
229. Stand (JM8114) illustrating the Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t. of the IB3 Ecosite.
230. General features of the Jonas 1 (JN1) Ecosite.
231. Pedon (Alberta 1977 No. 128) description of an Eluviated Dystric Brunisol of the JN1 Ecosite.
232. Stand (PA7143) illustrating the heather-everlasting (L5) v.t. of the JN1 Ecosite.
233. General features of the Katherine 1 (KA1) Ecosite.
234. Pedon (Alberta 1979 No. 90) description of a Cumulic Humic Regosol of the KA1 Ecosite.
235. Stand (JD9081) illustrating the arctic willow-cinquefoil (L7) v.t. of the KA1 Ecosite.
236. General features of the Larch Valley (LV) Ecosites.
237. Pedon (Alberta 1978 No. 96) description of an Eluviated Dystric Brunisol of the LV1 Ecosite.
238. Stand (JE8157) illustrating the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. of the LV1 Ecosite.
239. Pedon (Alberta 1979 No. 45) description of an Eluviated Dystric Brunisol of the LV2 Ecosite.
240. Stand (PA9125) illustrating the Engelmann spruce-subalpine fir/heather (O10) portion of the v.t. pattern of the LV2 Ecosite.
241. Pedon (Alberta 1979 No. 52) description of an Eluviated Dystric Brunisol of the LV3 Ecosite.
242. Stand (JC7080) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the LV3 Ecosite.
243. General features of the Merlin Castle 1 (MC1) Ecosite.
244. Pedon (Alberta 1977 No. 126) description of a Gleyed Eutric Brunisol of wet segments of the MC1 Ecosite.
245. Stand (AW7073) illustrating the spruce/Labrador tea/brown moss (O11) v.t. of wet segments of the MC1 Ecosite.
246. General features of the Moraine Lake (ML) Ecosites.
247. Pedon (Alberta 1974 No. 124) description of an Eluviated Dystric Brunisol of the ML1 Ecosite.
248. Stand (KS5052) illustrating the Engelmann spruce-subalpine fir/false azalea (C14) v.t. of the ML1 Ecosite.
249. Pedon (Alberta 1979 No. 60) description of an Eluviated Dystric Brunisol of the ML2 Ecosite.
250. Stand (IC6003) illustrating the lodgepole pine/false azalea/grouseberry (C20) v.t. of the ML2 Ecosite.
251. Stand (IC5073) illustrating the Engelmann spruce-whitebark pine/false azalea (C12) v.t. of the ML3 Ecosite.
252. General features of the Molar Pass 1 (MP1) Ecosite.
253. Pedon (Alberta 1979 No. 92) description of an Orthic Eutric Brunisol of the MP1 Ecosite.
254. Stand (JD9083) illustrating the mountain avens-snow willow-moss campion (H1) v.t. of the MP1 Ecosite.
255. General features of the Mosquito 1 (MQ1) Ecosite.
256. Pedon (Alberta 1977 No. 159) description of an Orthic Eutric Brunisol of the MQ1 Ecosite.
257. Stand (PA7186) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the MQ1 Ecosite.

258. General features of the Nigel 1 (NG1) Ecosite.
259. Pedon (Alberta 1979 No. 86) description of an Eluviated Eutric Brunisol of the NG1 Ecosite.
260. Stand (JD9077) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the NG1 Ecosite.
261. General features of the Nashan 1 (NH1) Ecosite.
262. Pedon (Alberta 1979 No. 28) description of a Rego Gleysol from wet segments of the NH1 Ecosite.
263. Pedon (Alberta 1979 No. 29) description of a Brunisolic Gray Luvisol from dry upland segments of the NH1 Ecosite.
264. Stand (JD9021) illustrating the spruce/Labrador tea/brown moss (O11) v.t. of wet segments of the NH1 Ecosite.
265. General features of the Num-Ti-Jah (NT) Ecosites.
266. Pedon (Alberta 1979 No. 77) describing a Rego Gleysol of the NT2 Ecosite.
267. Stand (IC6021) illustrating the willow-cinquefoil (S8) v.t. of the NT2 Ecosite.
268. Pedon (Alberta 1979 No. 50) describing a Terric Mesisol of the NT3 Ecosite.
269. Stand (SJ9134) illustrating the water sedge-beaked sedge (H11) v.t. of the NT3 Ecosite.
270. General features of the Norquay (NY) Ecosites.
271. Pedon (Alberta 1977 No. 141) describing an Orthic Eutric Brunisol of the NY1 Ecosite.
272. Stand (PA7193) illustrating the lodgepole pine/buffaloberry/showy aster (C6) v.t. of the NY1 Ecosite.
273. Pedon (Alberta 1978 No. 85) describing an Orthic Eutric Brunisol of northerly aspect segments of the NY3 Ecosite.
274. Pedon (Alberta 1978 No. 84) describing an Orthic Regosol of southerly aspect segments of the NY3 Ecosite.
275. Stand (JC8002) illustrating the white spruce-Douglas fir/feathermoss (C5) v.t. of northerly aspect segments of the NY3 Ecosite.
276. Stand (JC8001) illustrating limber pine-Douglas fir/juniper/bearberry (O2), an accessory v.t. of southerly aspect segments of the NY3 Ecosite.
277. General features of the Peyto Lake (PL) Ecosites.
278. Pedon (Alberta 1977 No. 147) describing an Orthic Eutric Brunisol of the PL1 Ecosite.
279. Stand (AW5137) illustrating the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. of the PL1 Ecosite.
280. Pedon (Alberta 1978 No. 79) description of an Eluviated Eutric Brunisol of the PL3 Ecosite.
281. Stand (JE8161) illustrating the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. of the PL3 Ecosite.
282. Pedon (Alberta 1979 No. 67) description of an Eluviated Eutric Brunisol of the PL4 Ecosite.
283. Stand (LC9182) illustrating the Engelmann spruce-subalpine fir/heather (O10) portion of the v.t. pattern of the PL4 Ecosite.
284. Pedon (Alberta 1978 No. 63) description of a gleyed Humo-Ferric Podzol of wet depressional segments of the PL5 Ecosite.
285. Stand (PA8170) illustrating the willow/timber oatgrass (S11) v.t. of wet depressional segments of the PL5 Ecosite.
286. General features of the Pipestone (PP) Ecosites.
287. Pedon (Alberta 1975 No. 104) description of a Cumulic Regosol of the PP1 Ecosite.
288. Stand (KS5138) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the PP1 Ecosite.
289. Stand (JD9006) illustrating the balsam poplar/buffaloberry (C17) v.t. of the PP2 Ecosite.
290. Pedon (Alberta 1978 No. 92) description of a Cumulic Regosol of the PP3 Ecosite.
291. Stand (JC8085) illustrating the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. of the PP3 Ecosite.
292. Pedon (Alberta 1978 No. 20) description of an Orthic Regosol of the PP4 Ecosite.
293. Stand (IC8093) illustrating the yellow dryad-willowherb (H8) v.t. of the PP4 Ecosite.
294. Pedon (Alberta 1979 No. 85) description of an Orthic Regosol of the PP6 Ecosite.
295. Stand (JD9076) illustrating the Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) v.t. of the PP6 Ecosite.
296. Pedon (Alberta 1979 No. 55) description of an Orthic Humic Regosol of the PP7 Ecosite.
297. Stand (PA9117) illustrating the dwarf birch-willow/kobresia (S9) v.t. of the PP7 Ecosite.
298. General features of the Panorama Ridge (PR) Ecosites.
299. Pedon (Alberta 1979 No. 63) description of an Eluviated Eutric Brunisol of the PR1 Ecosite.
300. Stand (SJ9128) illustrating the lodgepole pine/false azalea/grouseberry (C20) v.t. of the PR1 Ecosite.
301. Pedon (Alberta 1979 No. 43) description of an Eluviated Eutric Brunisol of the PR2 Ecosite.
302. Stand (LC9023) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the PR2 Ecosite.
303. Pedon (Alberta 1976 No. 96) description of a Gleyed Brunisolic Gray Luvisol of the PR3 Ecosite.
304. Stand (KS5015) illustrating the lodgepole pine/buffaloberry/grouseberry (C18) v.t. of the PR3 Ecosite.
305. Pedon (Alberta 1978 No. 64) description of an Eluviated Eutric Brunisol from southerly aspect segments of the PR4 Ecosite.
306. Stand (JE8003) illustrating the lodgepole pine/juniper/bearberry (C3) v.t. of southerly aspect segments of the PR4 Ecosite.

307. Pedon (Alberta 1978 No. 67) description of an Eluviated Eutric Brunisol of the PR6 Ecosite.
308. Stand (JE8005) illustrating the lodgepole pine/feathermoss (C11) v.t. of the PR6 Ecosite.
309. General features of the Patricia (PT) Ecosites.
310. Pedon (Alberta 1978 No. 86) description of an Eluviated Eutric Brunisol of the PT1 Ecosite.
311. Stand (AW6037) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the PT1 Ecosite.
312. Pedon (Alberta 1979 No. 21) description of an Eluviated Eutric Brunisol, lithic phase, of the PT3 Ecosite.
313. Stand (SJ9124) illustrating the lodgepole pine/juniper/bearberry (C3) v.t. of the PT3 Ecosite.
314. Stand (JE9177) illustrating the aspen/hairy wild rye-peavine (C16) v.t. of the PT4 Ecosite.
315. Stand (LC9179) illustrating the lodgepole pine/feathermoss (C11) v.t. of dry upland segments of the PT5 Ecosite.
316. Stand (LC9178) illustrating the black spruce-lodgepole pine/willow/sedge (C8) v.t. of wet depressional segments of the PT5 Ecosite.
317. General features of the Redoubt 1 (RD1) Ecosite.
318. Pedon (Alberta 1978 No. 54) description of an Orthic Regosol of the RD1 Ecosite.
319. Stand (JC8084) illustrating the heather-everlasting (L5) v.t. of the RD1 Ecosite.
320. General features of the Rocky 1 (RK1) Ecosite.
321. Stand (SJ9019) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the RK1 Ecosite.
322. General features of the Sawback (SB) Ecosites.
323. Pedon (Alberta 1978 No. 93) description of a Cumulic Humic Regosol of the SB1 Ecosite.
324. Stand (JC8086) illustrating the aspen/hairy wild rye-showy aster (C22) v.t. of the SB1 Ecosite.
325. Pedon (Alberta 1978 No. 35) description of an Orthic Eutric Brunisol of the SB2 Ecosite.
326. Stand (JE8150) illustrating the Engelmann spruce-subalpine fir/false azalea (C14) v.t. of the SB2 Ecosite.
327. Pedon (Alberta 1979 No. 25) description of an Orthic Eutric Brunisol of the SB3 Ecosite.
328. Stand (PA9132) illustrating the lodgepole pine-buffaloberry/showy aster (C6) v.t. of the SB3 Ecosite.
329. Pedon (Alberta 1978 No. 66) description of an Orthic Eutric Brunisol, lithic phase, of the SB4 Ecosite.
330. Stand (JC8004) illustrating an open variant of the lodgepole pine/juniper/bearberry (C3) v.t. of the SB4 Ecosite.
331. Pedon (Alberta 1979 No. 88) description of an Orthic Eutric Brunisol of the SB5 Ecosite.
332. Stand (JD9079) illustrating the hairy wild rye-junegrass-bearberry (H14) v.t. of the SB5 Ecosite.
333. General features of the Snowflake 1 (SF1) Ecosite.
334. Pedon (Alberta 1979 No. 66) description of a Regosolic Static Cryosol, turbic phase, of the SF1 Ecosite.
335. Stand (PA9134) illustrating the Engelmann spruce-subalpine fir/rock willow/white mountain heather (C24) v.t. of the SF1 Ecosite.
336. General features of the Spray 1 (SP1) Ecosite.
337. Pedon (Alberta 1976 No. 94) description of an Orthic Gray Luvisol of the SP1 Ecosite.
338. Stand (SJ8063) illustrating the lodgepole pine/Labrador tea (C29) v.t. of the SP1 Ecosite.
339. General features of the sphinx (SX) Ecosites.
340. Pedon (Alberta 1979 No. 40) description of an Orthic Gleysol of the SX1 Ecosite.
341. Stand (LC9167) illustrating the fleabane-valerian (H16) v.t. of the SX1 Ecosite.
342. Pedon (Alberta 1979 No. 46) description of a Gleyed Dystric Brunisol of the SX2 Ecosite.
343. Stand (PA9126) illustrating the Engelmann spruce-subalpine fir/valerian-fleabane (O9) v.t. of the SX2 Ecosite.
344. Pedon (Alberta 1978 No. 56) description of a gleyed Podzolic soil of the SX3 Ecosite.
345. Stand (JD8113) illustrating the willow-dwarf birch/fleabane (S4) v.t. of the SX3 Ecosite.
346. General features of the Talbot (TA) Ecosites.
347. Pedon (Alberta 1979 No. 64) description of an Orthic Regosol of the TA2 Ecosite.
348. Stand (SJ9001) illustrating the junegrass-pasture sage-wild blue flax (H6) v.t. of the TA2 Ecosite.
349. Pedon (Alberta 1977 No. 117) description of a Cumulic Regosol of the TA3 Ecosite.
350. Stand (JC7095) illustrating the white spruce/prickly rose/fern moss (C27) v.t. of the TA3 Ecosite.
351. General features of the Tekarra 1 (TK1) Ecosite.
352. Pedon (Alberta 1978 No. 78) description of an Orthic Dystric Brunisol of the TK1 Ecosite.
353. Stand (JC8092) illustrating the mountain avens-snow willow-moss campion (H1) v.t. of the TK1 Ecosite.
354. General features of the Tyrrell (TR) Ecosites.
355. Pedon (Alberta 1979 No. 53) description of an Orthic Eutric Brunisol of the TR1 Ecosite.
356. Stand (PA9115) illustrating the willow-dwarf birch-shrubby cinquefoil (S10) v.t. of the TR1 Ecosite.
357. Pedon (Alberta 1978 No. 101) description of an Orthic Eutric Brunisol of the TR2 Ecosite.
358. Stand (PA8167) illustrating the mountain avens-kobresia-bearberry (H4) v.t. of the TR2 Ecosite.
359. General features of the Topaz (TZ) Ecosites.
360. Pedon (Alberta 1979 No. 39) description of an Eluviated Dystric Brunisol of dry upland segments of the TZ2 Ecosites.

361. Stand (LC9165) illustrating the lodgepole pine-(Engelmann spruce)/crowberry/lichen (C35) v.t. of dry upland segments of the TZ2 Ecosite.
362. General features of the Verdant (VD) Ecosites.
363. Pedon (Alberta 1978 No. 28) description of an Eluviated Dystric Brunisol of the VD1 Ecosite.
364. Stand (JC9068) illustrating the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. of the VD1 Ecosite.
365. Stand (AW5056) illustrating the lodgepole pine/buffaloberry/twinflower (C19) v.t. of the VD2 Ecosite.
366. General features of the Vermilion Lakes (VL) Ecosites.
367. Pedon (Alberta 1976 No. 97) description of a Terric Mesisol of the VL1 Ecosite.
368. Stand (KS6054) illustrating the water sedge-beaked sedge (H11) v.t. of the VL1 and VL3 Ecosites.
369. Pedon (Alberta 1978 No. 87) description of a Rego Gleysol of the VL3 Ecosite.
370. Pedon (Alberta 1978 No. 30) description of a Rego Gleysol of the VL4 Ecosite.
371. Stand (JM8119) illustrating the white spruce/prickly rose/horsetail (C4) v.t. of the VL3 and VL4 Ecosites.
372. Pedon (Alberta 1978 No. 31) description of a Rego Gleysol of the VL5 Ecosite.
373. Stand (SJ8105) illustrating the willow/horsetail (S7) v.t. of the VL5 Ecosite.
374. General features of the Wildflower (WF) Ecosites.
375. Pedon (Alberta 1978 No. 75) description of an Orthic Eutric Brunisol of the WF1 Ecosite.
376. Stand (JC8090) illustrating the Engelmnn spruce-subalpine fir/tall bilberry/liverwort (C21) v.t. of the WF1 Ecosite.
377. Pedon (Alberta 1977 No. 131) description of a Cumulic Humic Regosol of the WF2 Ecosite.
378. Stand (JE9178) illustrating the subalpine fir-willow (S2) v.t. of the WF2 Ecosite.
379. Pedon (Alberta 1979 No. 65) description of an Orthic Eutric Brunisol of the WF3 Ecosite.
380. Stand (LC9181) illustrating the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) v.t. of the WF3 Ecosite.
381. Pedon (Alberta 1979 No. 93) description of an Orthic Eutric Brunisol of the WF4 Ecosite.
382. Stand (JD9084) illustrating the Engelmann spruce/hairy wild rye (C33) v.t. of the WF4 Ecosite.
383. Pedon (Alberta 1979 No. 97) description of an Orthic Melanic Brunisol of the WF7 Ecosite.
384. Stand (PA9139) illustrating the hairy wild rye-junegrass-bearberry (H14) v.t. of the WF7 Ecosite.
385. General features of the Whitehorn (WH) Ecosites.
386. Pedon (Alberta 1978 No. 82) description of an Orthic Sombric Brunisol of the WH1 Ecosite.
387. Stand (JC8097) illustrating the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. of the WH1 Ecosite.
388. Stand (LC9017) illustrating the Engelmann spruce-subalpine fir/heather (O10) v.t. of the WH2 Ecosite.
389. Pedon (Alberta 1979 No. 41) description of an Orthic Dystric Brunisol of the WH3 Ecosite.
390. Stand (LC9168) illustrating the subalpine fir-willow (S2) v.t. of the WH3 Ecosite.
391. Pedon (Alberta 1977 No. 125) description of an Orthic Regosol of the WH5 Ecosite.
392. Stand (AW7105) illustrating spotted saxifrage-hairy wild rye (H20), a v.t. occurring in minor amounts on actively colluviating portions of the WH5 Ecosite.
393. General features of the Warwick 1 (WW1) Ecosite.
394. Pedon (Alberta 1978 No. 103) description of an Orthic Humic Regosol of the WW1 Ecosite.
395. Stand (PR8169) illustrating the yellow dryad-willowherb (H8) v.t. of the WW1 Ecosite.

LIST OF PLATES

Frontispiece. Mount Rundle and Vermilion Lakes: an example of the variety of biophysical resources found in Banff and Jasper National Parks.

1. Postglacial residual genetic material on Copper Mountain, Banff.
2. Dip slope failure near Nigel Pass in Jasper; with potential for further failure.
3. Debris cones on a landslide of unconsolidated material; near Dolomite Creek, Banff.
4. An exposure of Ice Contact Stratified Drift B. Note vertical and lateral textural variability, the coarse textures being associated with the gravelly surface and the pocket at the left (under spade), medium textures with the unsorted material. Near Mistaya Canyon bridge, Banff.
5. An abrupt vegetation boundary bordering an active glaciofluvial area at the confluence of Conway, Forbes, and Freshfield Creeks with the Howse River, Banff.
6. *Pseudotsuga menziesii/Elymus innovatus* (C1) v.t. at 1160 m in central Jasper (IC5022.1).
7. *Picea glauca/Thuidium abietinum* (C2) v.t. at 1100 m on a gentle northwest aspect near the east gate of Jasper (JC7009.1).
8. *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi* (C3) v.t. at 1490 m in southern Banff (JD7114).
9. *Picea glauca/Rosa acicularis/Equisetum arvense* (C4) v.t. at 1000 m in central Jasper (JM8119).
10. *Picea glauca-Pseudotsuga menziesii/Hylocomium splendens* (C5) v.t. in northern Banff.
11. *Pinus contorta/Shepherdia canadensis/Aster conspicuus* (C6) v.t. at 1750 m in central Banff (PA8153).
12. *Picea mariana-Pinus contorta/Salix myrtillifolia/Carex vaginata* (C8) v.t. at 1230 m in central Jasper (JC6008).
13. *Pinus contorta/Alnus crispa/Hylocomium splendens* (C10) v.t. at 1420 m on a moderate easterly aspect in central Jasper (IC5072).
14. *Pinus contorta/Hylocomium splendens* (C11) v.t. at 1320 m in central Jasper (JC6004).
15. *Picea engelmannii-Abies lasiocarpa/Hylocomium splendens* (C13) v.t. in southern Jasper.
16. *Picea engelmannii-Abies lasiocarpa/Menziesia glabella* (C14) v.t. at 1760 m in northern Banff (PA7054).
17. *Picea engelmannii-Abies lasiocarpa/Vaccinium scoparium* (C15) v.t. at 2080 m in northern Banff (JD9077).
18. *Populus tremuloides/Elymus innovatus-Lathryus ochroleucus* (C16) v.t. at 1450 m in southern Banff (PA8001.5).
19. *Populus balsamifera/Shepherdia canadensis* (C17) v.t. at 1230 m near the east gate of Jasper (JC7011).
20. *Pinus contorta/Shepherdia canadensis/Vaccinium scoparium* (C18) v.t. at 1500 m in northern Banff (JC6011).
21. *Pinus contorta/Shepherdia canadensis/Linnaea borealis* (C19) v.t. at 1480 m in southern Banff (JE8004).
22. *Pinus contorta/Merziesia glabella/Vaccinium scoparium* (C20) v.t. at 1530 m in western Jasper (JD9030).
23. *Picea engelmannii-Abies lasiocarpa/Vaccinium membranaceum/Barbilophozia lycopodioides* (C21) v.t. at 1890 m in northern Banff (JC6112).
24. *Populus tremuloides/Elymus innovatus-Aster conspicuus* (C22) v.t. on a steep west aspect in northern Banff (IC6022).
25. *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata* (C23) v.t. at 2250 m in central Banff.
26. *Picea engelmannii-Abies lasiocarpa/Salix vestita/Cassiope tetragona* (C24) v.t. at 2020 m on a steep north aspect in northern Jasper (PA9134).
27. *Picea glauca/Shepherdia canadensis/Thuidium abietinum* (C26) v.t. at 1470 m in northern Banff (PA7059).
28. *Picea glauca/Rosa acicularis/Thuidium abietinum* (C27) v.t. at 1000 m near the east gate of Jasper (JM8001).
29. *Pinus contorta/Ledum groenlandicum* (C29) v.t. at 1590 m in southern Banff (PA7012).
30. *Picea engelmannii-Abies lasiocarpa/Ledum groenlandicum/Empetrum nigrum* (C30) v.t. at 1510 m in central Jasper (JM8114).
31. *Picea engelmannii-Abies lasiocarpa/Elymus innovatus-Arnica cordifolia-Linnaea borealis/Hylocomium splendens* (C31) v.t. at 1510 m in northern Jasper (PA9031).
32. *Picea engelmannii/Equisetum arvense/Hylocomium splendens* (C32) v.t. at 1670 m in northern Jasper (PA9051).
33. *Picea engelmannii/Elymus innovatus* (C33) v.t. at 1990 m in eastern Banff (JE8015).
34. *Picea engelmannii-Abies lasiocarpa/Phyllodoce glanduliflora/Hylocomium splendens* (C34) v.t. at 1900 m in western Jasper (PA9113).
35. *Pinus contorta-(Picea engelmannii)/Empetrum nigrum/Cladonia mitis* (C35) v.t. in northern Jasper.
36. *Pinus flexilis-Pseudotsuga menziesii/Juniperus scopulorum/Arctostaphylos uva-ursi* (O2) v.t. at 1420 m in southern Banff (JC8001).
37. *Picea glauca/Potentilla fruticosa/Arctostaphylos uva-ursi* (O3) v.t. at 1000 m near the east gate of Jasper (SJ8003).
38. *Picea engelmannii-Abies lasiocarpa-Pinus albicaulis-Pinus contorta* (O4) v.t. at 2040 m on a steep southwest aspect in central Jasper (LC9181).
39. *Pseudotsuga menziesii/Juniperus* spp./*Arctostaphylos uva-ursi* (O5) v.t. at 1410 m in southern Banff.
40. *Picea engelmannii-Abies lasiocarpa/Salix* spp./*Aulacomnium palustre* (O6) v.t. at 1920 m in central Banff (PA7029).

41. *Picea engelmannii-Abies lasiocarpa/Valeriana sitchensis-Erigeron peregrinus* (O9) v.t. at 2000 m in northern Jasper (PA9078). This stand also contains much *Lupinus nootkatensis*.
42. *Picea engelmannii-Abies lasiocarpa/Phyllodoce glanduliflora-Cassiope mertensiana* (O10) v.t. at 2100 m in northern Banff (PA8161).
43. *Picea* spp./*Ledum groenlandicum/Tomenthypnum nitens* (O11) v.t. at 1270 m near the east gate of Jasper (JD9021).
44. *Picea engelmannii-Abies lasiocarpa/Salix vestita/Arctostaphylos rubra* (O12) v.t. at 2040 m in northern Banff (JC6102.2).
45. *Picea engelmannii-Abies lasiocarpa/Salix vestita/Pedicularis bracteosa* (O14) v.t. at 2110 m in eastern Banff (JC8012.1).
46. *Betula papyrifera-Betula occidentalis/Arctostaphylos uva-ursi* (O16) v.t. at 1200 m on a steep southwest aspect near the east gate of Jasper (IC7002).
47. *Picea glauca/Juniperus communis/Arctostaphylos uva-ursi* (O17) v.t. at 1780 m on a steep west aspect in northern Banff (JE8135).
48. *Picea engelmannii-Abies lasiocarpa/Salix glauca/Elymus innovatus* (O18) v.t. at 2170 m in eastern Banff (PA7037).
49. *Picea engelmannii-Abies lasiocarpa/Dryas octopetala* (O19) v.t. at 2350 m in eastern Banff (PA8012.2).
50. *Betula* spp.-*Potentilla fruticosa-Salix glauca/Tomenthypnum nitens* (S1) v.t. at 1380 m in northern Jasper (PA9011).
51. *Abies lasiocarpa-Salix* spp./*Valeriana sitchensis* (S2) v.t. in central Banff.
52. *Betula glandulosa-Potentilla fruticosa/Scirpus caespitosus/Drepanocladus revolvens* (S3) v.t. in northern Banff.
53. *Salix* spp.-*Betula glandulosa/Erigeron peregrinus* (S4) v.t. at 2100 m in central Jasper (IC5061).
54. *Salix scouleriana-Alnus crispa/Mertensia paniculata* (S6) v.t. at 1380 m in central Jasper (IC5019).
55. *Salix* spp./*Equisetum arvense* (S7) v.t. at 1000 m in central Jasper (SJ8105).
56. *Salix barrattiana/Potentilla diversifolia* (S8) v.t. at 2300 m in northern Banff (PA7133).
57. *Betula glandulosa-Salix glauca/Kobresia myosuroides* (S9) v.t. at 1850 m in southeast Jasper (PA9117).
58. *Salix glauca-Betula glandulosa-Potentilla fruticosa* (S10) v.t. at 2040 m on a steep southwest aspect in central Banff (PA7152.1).
59. *Salix glauca/Danthonia intermedia* (S11) v.t. at 2100 m in central Banff (PA7172).
60. *Salix glauca/Elymus innovatus* (S12) v.t. at 2080 m in northeast Banff (JC8076).
61. *Potentilla fruticosa/Arctostaphylos uva-ursi-Galium boreale* (L1) v.t. in eastern Banff.
62. *Juniperus communis/Salix glauca* (L2) v.t. at 2050 m on a steep southwest aspect in northern Jasper (PA9095).
63. *Cassiope tetragona/Dryas octopetala-Salix nivalis* (L4) v.t. at 2360 m in eastern Banff (JD7008).
64. *Phyllodoce glanduliflora-Cassiope mertensiana/Antennaria lanata* (L5) v.t. at 2240 m in western Jasper (SJ7076).
65. *Juniperus horizontalis/Agropyron dasystachyum-Carex scirpoidea* (L6) v.t near Talbot Lake in Jasper.
66. *Salix arctica/Potentilla diversifolia* (L7) v.t. at 2260 m in northern Jasper (JD9070).
67. *Dryas octopetala-Salix nivalis-Silene acaulis* (H1) v.t. at 2340 m in eastern Banff (JD7009).
68. *Carex nigricans-Antennaria lanata* (H2) v.t. in southern Jasper.
69. *Carex scipoidea-Saxifraga aizoides* (H3) v.t. in central Banff.
70. *Dryas octopetala-Kobresia myosuroides-Arctostaphylos uva-ursi* (H4) v.t. at 2330 m in western Jasper (IC6122).
71. *Elymus innovatus-Fragaria virginians-Epilobium angustifolium* (H5) v.t. at 1890 m on a steep southwest aspect in northern Banff (IC7030).
72. *Koeleria cristata-Artemisia frigida-Linum lewisii* (H6) v.t. at 1070 m in central Jasper (IC5003).
73. *Agropyron dasystachyum-Artemisia frigida* (H7) v.t. at 1140 m in central Jasper (IC5018).
74. *Dryas drummondii-Epilobium latifolium* (H8) v.t. at 1800 m in western Jasper (IC6067.3).
75. *Caltha leptosepala-Trollius albiflorus* (H9) v.t. at 2150 m in central Jasper (JC7053).
76. *Eriophorum angustifolium/Drepanocladus revolvens* (H10) v.t. at 2320 m in northern Banff (PA8080).
77. *Carex aquatilis-Carex rostrata* (H11) v.t. at 1380 m in central Banff (vicinity KS6054).
78. Saxicolous lichen (H12) v.t. at 2630 m in central Banff (PA7021).
79. *Stipa richardsonii-Koeleria cristata-Antennaria nitida* (H13) v.t. at 1410 m in southern Banff (PA8000.2).
80. *Elymus innovatus-Koeleria cristata-Arctostaphylos uva-ursi* (H14) v.t. at 2380 m on a steep southeast aspect in eastern Banff (PA8012).
81. *Erigeron peregrinus-Valeriana sitchensis* (H16) v.t. in western Jasper.
82. Stereo-triplet of the Bow River valley at Baker Creek showing landscape stratification of Ecoregions and Ecoregion subunits.
83. Stereo-triplet of the Bow River valley at Baker Creek showing landscape stratification of genetic material units.
84. Stereo-triplet of the Bow River valley at Baker Creek showing detail of landscape stratification into Ecosite units.
85. *Pinus contorta/Shepherdia canadensis/Linnaea borealis* (C19) v.t. on Altrude 1 Ecosite (AL1).

86. *Picea engelmannii-Abies lasiocarpa/Hylocomium splendens* (C13) v.t. on Altrude 2 Ecosite (AL2).
87. Complex slopes producing the dry-wet drainage pattern of the AZ1 Ecosite.
88. BK1 sample site showing a *Pinus contorta/Shepherdia canadensis/Vaccinium scoparium* (C18) v.t. stand of dry upland segments; described in Tables 112 and 114.
89. BK4 dry upland segment pedon site described in Table 116.
90. Wet depressional segment common on BK Ecosites, showing shrub thicket vegetation.
91. BP1 sample site showing landform and a *Picea engelmannii-Abies lasiocarpa-Pinus albicaulis-Pinus contorta* (O4) v.t. stand.
92. BP2 sample site showing a *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata* (C23) v.t. stand.
93. BS1 landscape at Pipestone Pass in Banff.
94. BV1 sample site showing a *Pinus contorta/Shepherdia canadensis/Linnaea borealis* (C19) v.t. stand.
95. BY2 sample site showing a *Picea engelmannii-Abies lasiocarpa/Elymus innovatus-Arnica cordifolia-Linnaea borealis/Hylocomium splendens* (C31) v.t. stand.
96. BY4 pedon sample site.
97. BZ2 sample site showing a *Pinus contorta/Ledum groenlandicum* (C29) v.t. stand.
98. CA1 wet segment pedon sample site.
99. CP1 sample site showing a *Picea engelmannii-Abies lasiocarpa/Vaccinium scoparium* (C15) v.t. stand.
100. CV1 wet segment pedon sample site.
101. Active Eolian material A in the Athabasca River valley in Jasper.
102. DV1 landscape.
103. Blowout area on DV1 near Jasper Lake.
104. EF1 landscape with typically stony surface.
105. Landscape of EG1 and EG2 (background) and SX1 (foreground) in Lost Horse Creek, Banff.
106. EG2 sample site showing an open variant of a *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata* (C23) v.t. stand.
107. EN1 sample site showing a *Picea engelmannii-Abies lasiocarpa/Vaccinium scoparium* (C15) v.t. stand.
108. EN2 sample site showing an *Abies lasiocarpa-Salix* spp./*Valeriana sitchensis* (S2) v.t. stand.
109. EN3 sample site showing a *Picea engelmannii-Abies lasiocarpa-Pinus albicaulis-Pinus contorta* (O4) v.t. stand.
110. FR1 sample site showing a *Pinus contorta/Shepherdia canadensis/Aster conspicuus* (C6) v.t. stand.
111. FV1 sample site showing an *Abies lasiocarpa-Salix* spp./*Valeriana sitchensis* (S2) v.t. stand.
112. FV2 sample site showing a *Picea engelmannii-Abies lasiocarpa/Hylocomium splendens* (C13) v.t. stand.
113. GA1 landscape in Jasper.
114. GT1 sample site showing an open variant of a *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi* (C3) v.t. stand.
115. GT2 sample site showing a *Potentilla fruticosa/Arctostaphylos uva-ursi-Galium boreale* (L1) v.t. stand of southerly aspect segments.
116. HC2 in a valley floor landscape between Mistaya and Upper Waterfowl Lakes in Banff.
117. HC4 in the valley bottom of the upper Spray River in Banff.
118. HC1 sample site showing a *Picea engelmannii/Equisetum arvense/Hylocomium splendens* (C32) v.t. stand.
119. Sampled Rego Gleysol of the HC2 Ecosite.
120. HC2 pedon sample site.
121. HC2 pedon sample site showing a *Carex aquatilis-C.rostrata* (H11) v.t. stand.
122. HC4 sample site (Terric Mesisol) showing a *Betula glandulosa-Potentilla fruticosa/Scirpus caespitosus/Drepanocladus revolvens* (S3) v.t. stand.
123. HD1 sample site showing a *Populus tremuloides/Elymus innovatus-Lathyrus ochroleucus* (C16) v.t. stand.
124. HD3 sample site showing a *Picea glauca-Pseudotsuga menziesii/Hylocomium splendens* (C5) v.t. stand.
125. HD4 sample site showing a *Koeleria cristata-Artemisia frigida-Linum lewisii* (H6) v.t. stand.
126. HE1 landscape on the De Smet Range in Jasper.
127. HE1 pedon sample site.
128. HE2 in the landscape (lower foreground) in a hanging cirque above Rockbound Lake in Banff.
129. Landscape near the HE2 sample site.
130. Ground level view of part of the HE2 tract in Plate 128 showing how soil and water affect vegetation in HE2.
131. IB1 sample site showing a *Pinus contorta/Shepherdia canadensis/Vaccinium scoparium* (C18) v.t. stand.
132. JN1 pedon sample site.
133. KA1 sample site showing a *Salix arctica-Potentilla diversifolia* (L7) v.t. stand.
134. LV1 sample site showing a *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata* (C23) v.t. stand.

135. LV2 sample site showing the *Phyllodoce glanduliflora-Cassiope mertensiana-Antennaria lanata* (L5) and *Picea engelmannii-Abies lasiocarpa/Phyllodoce glanduliflora-Cassiope mertensiana* (O10) pattern of v.t.s typical on LV2.
136. MC1 wet depressional segment pedon sample site.
137. Severely soliflucted and cryoturbated MP1F tract.
138. A soliflucted MP1 tract with little surface manifestation of solifluction.
139. MP1 sample site showing a *Dryas octopetala-Salix nivalis-Silene acaulis* (H1) v.t. stand.
140. NT2 pedon sample site.
141. NT3 sample site showing a *Carex aquatilis-C. rostrata* (H11) v.t. stand.
142. NY3 northerly aspect segment sample site showing a *Picea glauca-Pseudotsuga menziesii/Hylocomium splendens* (C5) v.t. stand.
143. PL3 sample site showing a *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata* (C23) v.t. stand.
144. PL4 sample site showing a *Picea engelmannii-Abies lasiocarpa/Phyllodoce glanduliflora-Cassiope mertensiana* (O10) v.t. stand.
145. PL5 wet depression segment sample site showing a *Salix glauca/Danthonia intermedia* (S11) v.t. stand.
146. PP3 sample site showing *Picea engelmannii-Abies lasiocarpa/Hylocomium splendens* (C13) v.t. stand.
147. PP4 sample site showing a *Dryas drummondii-Epilobium latifolium* (H8) v.t. stand.
148. PP6 sample site showing a *Picea engelmannii-Abies lasiocarpa/Salix glauca/Elymus innovatus* (O18) v.t. stand.
149. PR2 pedon sample site.
150. PR3 pedon sample site showing a *Pinus contorta/Shepherdia canadensis/Vaccinium scoparium* (C18) v.t. stand.
151. PR4 southerly aspect segment sample site showing a *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi* (C3) v.t. stand.
152. PR6 pedon sample site showing a *Pinus contorta/Hylocomium splendens* (C11) v.t. stand.
153. PT3 sample site showing a *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi* (C3) v.t. stand.
154. Sampled stand of the *Populus tremuloides/Elymus innovatus-Lathyrus ochroleucus* (C16) v.t. on PT4.
155. RD1 pedon sample site showing a *Salix arctica-Potentilla diversifolia* (L7) v.t. stand.
156. SB1 sample site showing a *Populus tremuloides/Elymus innovatus-Aster conspicuus* (C22) v.t. stand.
157. SB3 sample site showing a *Pinus contorta/Shepherdia canadensis/Aster conspicuus* (C6) v.t. stand.
158. SB4 sample site showing an open variant of a *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi* (C3) v.t. stand.
159. SB5 sample site showing an *Elymus innovatus-Koeleria cristata-Arctostaphylos uva-ursi* (H14) v.t. stand.
160. SF1 in a landscape near Mount Sassenach in Jasper.
161. The influence of aspect on the distribution of Ecosites in Front Ranges areas underlain by Mesozoic strata.
162. Unconfined surface flow from spring snow melt on a SX1 tract.
163. Herb dominated SX1 and forested SX2 in the Miette (Centre) Pass area of Jasper.
164. SX1 sample site showing an *Erigeron peregrinus-Valeriana sitchensis* (H16) v.t. stand.
165. SX2 sample site showing a *Picea engelmannii-Abies lasiocarpa/Valeriana sitchensis-Erigeron peregrinus* (O9) v.t. stand.
166. SX3 pedon sample site showing a *Betula* spp.-*Potentilla fruticosa/Salix glauca/Tomenthypnum nitens* (S1) v.t. stand.
167. TA2 in a landscape near Moosehorn Creek in Jasper.
168. TA2 sample site showing a *Koeleria cristata-Artemisia frigida-Linum lewisii* (H6) v.t. stand.
169. TA3 sample site showing a *Picea glauca/Rosa acicularis/Thuidium abietinum* (C27) v.t. stand.
170. TK1 sample site showing a *Dryas octopetala-Salix nivalis-Silene acaulis* (H1) v.t. stand.
171. TR1 in a landscape near Arcturus Peak in Jasper.
172. Fire boundary (left centre) demarcating a shrub dominated TR1 tract from the forested SF1 tract.
173. TR1 sample site showing a *Salix glauca-Betula glandulosa-Potentilla fruticosa* (S10) v.t. stand.
174. TR2 sample site showing a *Dryas octopetala-Kobresia myosuroides-Arctostaphylos uva-ursi* (H4) v.t. stand.
175. TZ2 dry upland segment sample site showing a *Pinus contorta-(Picea engelmannii)/Empetrum nigrum/Cladonia mitis* (C35) v.t. stand.
176. VL1 and VL3 in a valley floor landscape near Banff townsite.
177. VL3 pedon sample site showing a *Picea glauca/Rosa acicularis/Equisetum arvense* (C4) v.t. stand.
178. WF1 sample site showing a *Picea engelmannii-Abies lasiocarpa/Vaccinium membranaecum/Barbilophozia lycopodioides* (C21) v.t. stand.
179. WF2 pedon sample site showing an *Abies lasiocarpa-Salix* spp./*Valeriana sitchensis* (S2) v.t. stand.
180. WF4 sample site showing a *Picea engelmannii/Elymus innovatus* (C33) v.t. stand.
181. WF7 sample site showing the *Elymus innovatus-Koeleria cristata-Arctostaphylos uva-ursi* (H14) v.t. stand.

182. WH1 sample site showing a *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata* (C23) v.t. stand.
183. WH3 in a landscape near Miette Pass in Jasper.
184. WH3 landscape near Whitehorn Mountain in Banff showing an *Abies lasiocarpa-Salix* spp./*Valeriana sitchensis* (S2) v.t. stand.
185. WH5 sample site showing a *Saxifraga bronchialis-Elymus innovatus* (H20) v.t. stand.
186. WW1 sample site showing a *Dryas drummondii-Epilobium latifolium* (H8) v.t. stand.
187. Snow avalanche paths modifying a BY1 tract (BY1A) in Arctomys Creek valley, Banff.
188. Fire modified PR4 tract (PR4B) near Vermilion Pass, Banff.
189. Fire modified PL1 and PL3 tracts (PL1B, PL3B) on Cascade Mountain, Banff.
190. Failing slope on a WF7 tract (WF7F) in Tyrrell Creek valley, Banff.
191. PL4 tract dominated by lithic soils (PL4X) in the Sunset Pass area of Banff.
192. A Colluvial Landslide (CL) above Baker Creek in Banff.
193. A Colluvial Rubble (CR) landscape near Tangle Ridge, Jasper.
194. Glacier (GL) in a landscape on Mount Wilson in Banff.

ABSTRACT

Banff and Jasper National Parks occupy about 17,520 km^2 (6765 mi^2) in Canada's southern Rocky Mountains. The area extends from approximately 53° 30' N and 119° 30' W at the northwest corner of Jasper to about 50° 40' N and 115° 20' W at the southern extremity of Banff. It is bounded on the west by the Continental Divide. The Ecological (Biophysical) Land Classification of Banff and Jasper presents landform, soil, and vegetation information in a map and descriptive format at a scale of 1:50,000 using a legend that integrates the three resource components in a holistic fashion. A three-level, hierarchical land classification system was developed using established landform and soil taxonomies, plus a classification of 85 vegetation types developed by the authors. The three levels are based on existing guidelines for Ecological (Biophysical) Land Classification in Canada and include, from highest to lowest level of generalization, Ecoregion, Ecosection, and Ecosite.

Ecoregion separations are based primarily on vegetation physiognomy and species composition which reflect macroclimate. Montane, Subalpine, and Alpine Ecoregions are recognized and mapped at a scale of 1:750,000 in this volume. The Subalpine Ecoregion is subdivided into Lower Subalpine and Upper Subalpine portions based on vegetational characteristics reflecting macroclimatic differences.

The Ecoregions are divided into 55 Ecosections. Ecosection separations are based on broad landform, drainage class, and soil differences. Landforms are comprised of ten genetic materials that have been divided into twenty genetic material units based on broad textural and chemical (calcareousness /reaction) differences.

The Ecosections are further separated into 124 Ecosites based on specific soil and vegetational differences that are considered insufficient, in magnitude or kind, to warrant separation at the Ecosection level. The Ecosites, plus eight Miscellaneous Landscapes, are the mapping units delineated on the twenty-four 1:50,000 maps. The landform, soil, and vegetation of each Ecosite are described in detail in this volume.

PREFACE

As part of a resource inventory of Banff and Jasper National Parks, Parks Canada initiated an Ecological (Biophysical) Land Classification of the two parks in May 1974. The classification includes data pertaining to the characteristics and distribution of landforms, soils, vegetation and wildlife of Banff and Jasper. The results of the classification study are presented in this report.

The report contains generalized and detailed descriptions of the landform, soil, vegetation, and wildlife resources. It has four main components. Volume I is a summary account of landforms, soils, vegetation and wildlife. Volume II provides detailed descriptions of the landforms, soils, and vegetation . Volume III is devoted entirely to wildlife. The fourth part of the report is a Map Supplement, containing 24 maps (scale 1:50,000) of the Ecological (Biophysical) Land Classification information.

The complete report is comprised of the written text of Volumes I, II, and III, plus the maps. To obtain the most complete information, all components should be used as an integral unit. The information in this report is scale dependent so site specific management decisions should be made in consultation with the appropriate specialists. Copies of the annotated air photos used in the field are filed with the Resources Studies Manager in the Western Region Office, Parks Canada, Calgary. In addition, the data are stored in a computer storage bank, CanSIS (Canada Soil Information System), Land Resource Research Institute, Ottawa.

Volume I is a summary overview of the Ecological (Biophysical) Land Classification of Banff and Jasper National Parks, including maps and legends, and is designed to provide a general approximation of the landform, soil, vegetational, and wildlife resources of the parks. Volume II contains a detailed account of the soils and vegetation information collected during the project. The encyclopedic style of Volume II was adopted to allow the readers to consult the report on the subject of immediate interest without necessarily reading it from the front.

Chapter I of Volume II describes the physical environment of Banff and Jasper, starting with climate and its relationship to land. A description of the physiography and topography provides a broad setting in Canada's Southern Rocky Mountains, including information on hydrology. An account of the geology and geomorphology completes the description of the physical setting.

Chapter II reviews previous soils work in the parks and presents field and laboratory methodologies. The soil Orders encountered and their distribution are also outlined.

Chapter III concerns vegetation. The study methodology is described, as are 85 vegetation types (v.t.s), a key to v.t. identification, an overview of community succession, and special and significant species. A checklist of vascular and nonvascular plants is in Appendix A.

Chapter IV provides an ecological integration of the physical and vegetational resources. Here, 55 Ecosections and 124 Ecosites, occurring in three Ecoregions, are described in detail with respect to ecological concept, landform, soils, and vegetational components.

ACKNOWLEDGEMENTS

The Ecological (Biophysical) Land Classification of Banff and Jasper was conducted jointly by the following agencies:

Environment Canada
- Canadian Forestry Service, Northern Forest Research Centre, Edmonton
- Canadian Wildlife Service, Banff, Jasper, and Edmonton

Agriculture Canada
- Alberta Pedology Unit, Land Resource Research Institute

Alberta Institute of Pedology
- located at the University of Alberta, Edmonton.

Major funding was provided by Parks Canada. Assistance provided by the Western Region Office, Parks Canada, Calgary is acknowledged, in particular: P.A. Benson, D.L. Day, J.C. Holroyd, K.E. Seel, and C. Zinkan.

The authors also express their appreciation for the cooperation and assistance of A.S. Anderson, D.A. Dumpleton, R.T. Flanagan, R.J. Haney, P.A. Lange, D.J. Martin, T.L. Ross, J.T. Steele, P. Whyte, E.B. Wilson, T.R. Wilson, D.J. Woodrow, and to all the wardens in both parks.

Thanks go to the following for assistance in plant identification: G. W. Argus, M. Barkworth, I. Brodo, N.H. Holmgren, D.G. Horton, G.A. Mulligan, M. Ostafichuk, J.G. Packer, T. Reeves, and D.H. Vitt.

Recognition is extended for assistance in the field and office by: T.V. Angen, R.A. Blundon, L. Cole, J.R. Cuddeford, J.R. Dyck, P.F. Epp, I.T. Fischer, E. Heacock, T.E. Hilborn, J.E. Marsh, G.E. McEwen, S.J. Scott (Davis), J. Tajek, and A.L. Westhaver. Special recognition is due R.E. Wells and S. Kojima for their contributions to the land classification in its earlier stages, and to B.J. Berteau for her contributions to computer data management and report production. D.J. Egglestone, W.C. McKean, and A. Schwartzer conducted soil laboratory analyses.

The following students provided short term assistance: J. Blythe, C. Chernoff, C. Epp, N.M. Finlayson, R.M. Hinkley, D.D. Holland, R.D. Holland, J.D. Johnson, J.E. McLean, R.L. McNeil, G.R. Moyse, D.E. Peters, P.T. Sanborn, C.A.S. Smith, G.A. Spiers, and B. Venner.

Excellent service was provided by helicopter pilots J. Davies, G. Forman, and K. Ostertag.

The cooperation of the Canadian Wildlife Service is acknowledged, particularly D. Karasiuk, G. Holroyd, and K. Van Tighem.

The Land Resource Research Institute contributed in two ways. First, in the drafting of the 24 maps by B. Edwards and the Cartography Section; and secondly, in assisting in the development of the data bank through the services of the Canada Soil Information System (CanSIS).

The assistance of the Canadian Forestry Service, including G.T. Silver, R.W. Reid, and administrative staff, is acknowledged. Special thanks must go to W. Chow and N. Leenders for computer services, to P. Debnam for photographic assistance, and to the stenographic pool.

INTRODUCTION

Banff and Jasper National Parks form a crude parallelogram in the southern Rocky Mountains of Canada along the southwestern border of Alberta (Fig. 1). The parks extend southeast for 425 km from approximately 53°30′ N and 119°30′ W at the northwestern corner of Jasper to about 50°40′ N and 115°20' W at the southern extremity of Banff. They are bounded on the west by the Continental Divide and range in width from approximately 106 km to about 10 km. Jasper occupies 10,880 km² (4,200 mi²), while Banff contains 6,640 km² (2,565 mi²).

Chapter 1 describes the physical environment, including climate, physiography, geology, and geomorphology. The climatic section describes temperature, precipitation, and wind variability across the landscape, with particular reference to the three major climatic units (Ecoregions).

The physiography section provides a general setting for the other landscape components, particularly geology and geomorphology, and the ecological mapping units (Ecosites). It also contains a general hydrological description of the area.

The geology and geomorphology sections present information on the stratigraphic and structural frameworks of Banff and Jasper, and how these influence the geomorphic materials. Of particular importance is the relationship between bedrock lithology and the textural and chemical properties of mineral genetic materials.

The geomorphology section deals with landform classification. It identifies four groups of genetic material and, within the unconsolidated mineral group, differentiates ten genetic material classes according to mode of origin. These ten classes are divided into twenty genetic material units (see Landform Classification), named by mode of origin plus an alphabetical symbol, (e.g. Till A, Till B). The twenty units are differentiated by textural and chemical properties as outlined in the geology section. However, the geomorphology section provides the greatest detail on textural and chemical properties of the genetic material units and includes a discussion of their formation, modifying processes, and relationships to other landscape components. These genetic material units frequently differentiate mapping units in the Ecological Land Clasification legend, particularly at the Ecosection level.

CLIMATE

W.D. Holland, P.L. Achuff, and B.D. Walker

OVERVIEW

Climatic data for Banff and Jasper National Parks are scarce, especially for the Upper Subalpine and Alpine Ecoregions. Chapman (1952), Trewartha (1957), Bailey (1962), and Janz and Storr (1977) provide climatic overviews of the Canadian Rocky Mountains. In particular, Janz and Storr (1977) give the most detailed and recent analysis of climate for the contiguous mountain parks. Other sources such as the *Atlas of Alberta* (Govt. of Alberta and Univ. of Alberta 1969) and the *National Atlas of Canada* (Surveys and Mapping Branch 1972) point out the insufficiency of data and in some instances indicate erroneous information (e.g. the extent of permafrost).

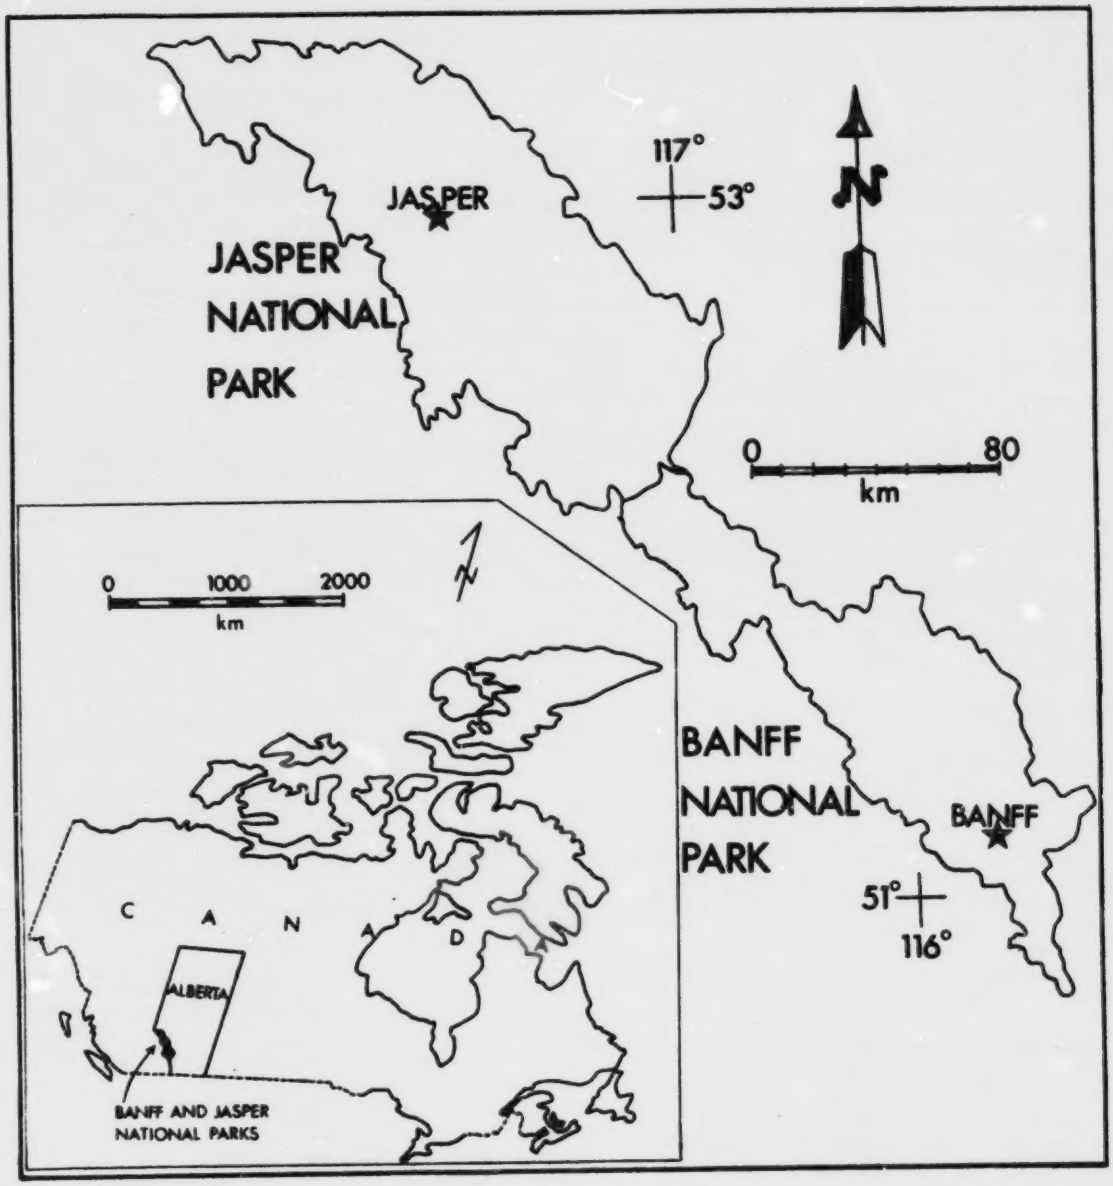

Figure 1 Location of study area.

Chapman (1952) and Heusser (1956) indicate that the Rocky Mountains inhibit westward movement of Polar Continental air but that cold air from the Yukon and Alaska easily moves parallel to the northwest-southeast trend of major valleys. Bailey (1962) criticizes Koeppen's climatic types because of limitations of map scale. Nevertheless, according to Koeppen's climate classification (Trewartha 1957) most of the valley bottoms and lower slopes of Banff and Jasper have a Dfc climate (Cold Snowy Forest Climate with no distinct dry season; cool short summers).

JANZ AND STORR'S STUDY (1977) ABSTRACTED

Location and Climate

The general climate of Banff and Jasper is determined chiefly by geographic location and topography. Geographic position considers latitude, proximity to oceans, and intervening mountain barriers. Latitude, ranging from 50°45' N to 53°30' N, determines the amount and distribution of solar energy plus

the nature and intensity of high and low pressure systems that migrate across the parks. The continental macroclimate of Banff and Jasper is a function of their position in the North American continent. They are located near the prairies, a considerable distance from the Pacific Ocean. Several major, intervening mountain ranges intercept some of the moisture carried by westerly winds. The absence of a major range to the east permits moisture from Hudson Bay, the Arctic Ocean and the Gulf of Mexico to reach the region.

Continental climate implies greater variability in seasonal and annual precipitation and temperature patterns than occurs in a maritime climate. In general, Banff and Jasper have long winters which can be cold, and short summers which are cool with occasional hot spells. Both parks are subject to the same air masses and weather systems that migrate across western Canada at mid-latitudes. The mountain topograhy, however, modifies and macroclimate creating mesoclimatic and microclimatic gradients. The mesoclimates are related to topography and several physiographic features of special importance.

Orientation of Mountain Ranges

The northwest-southeast orientation of the mountains and main valleys is almost at right angles to the prevailing winds aloft giving a rain shadow effect in main valleys. The generally low wind speeds in the valleys are also related to this orientation. However, wind speeds are higher where valleys, or portions of them, cut across the main northwest-southeast mountain ranges and in large valleys such as the lower Athabasca and Bow River valleys.

The Front Ranges and Foothills just east of Banff and Jasper block cold Arctic air from entering the parks. Arctic air plunging southward across the Alberta plains usually must enter Banff and Jasper through minor openings in the Front Ranges. Thus, outbreaks of cold are usually not as severe or as prolonged as on the prairies to the east. However, major valleys, such as the eastern portion of the Bow River valley, provide significant openings to the prairies and permit the intrusion of Arctic air. The Front Ranges are also effective in blocking "upslope" precipitation from reaching the interior of the parks.

Topography and Elevation

Topography and elevation influence the climate of Banff and Jasper by causing climatic variation over short distances. Variations in climate can occur with elevation changes of less than 100 m. Of particular importance is aspect. Significant vegetation and, in some areas, soil differences are related to northerly (northwest to east) versus southerly (southeast to west) aspect.

CLIMATE AND ECOREGIONS

Climatic elements such as solar radiation, wind, and precipitation provide the energy which is the basic driving force for ecosystems. Ecosystems consist of both biotic and physical components which interact to produce the landscape features of the parks. Climate, as part of the physical component, is influential in determining characteristics of other ecosystem components. Differences in climatic factors produce different ecosystems and ecosystem components. Lack of sufficient climatic data makes it impossible to classify Banff and Jasper, at scales of 1:250,000 and larger, using climatic data solely. Thus, vegetation has been used to indicate climatic units, since vegetation, as a biotic component of an ecosystem, strongly reflects climate. Many other factors besides climate influence vegetation. However, by dealing with vegetation at a high level of generalization, these other factors (slope, aspect, soil texture, fire, etc.) are less significant and the vegetation reflects mainly climate. Based primarily on vegetation physiognomy and composition, four units have been delineated: Montane Ecoregion, Subalpine Ecoregion (with Lower Subalpine and Upper Subalpine portions), and Alpine Ecoregion. An approximation of their distribution is shown in the section on Ecoregions, Chapter III. The following describes the climate of the units; for further descriptions of their vegetational definition and soil, landform and wildlife characteristics see appropriate portions of this report.

The most complete climatic data are available for the Montane, which is the smallest of the Ecoregions. Table 1 compares temperature and precipitation data of Banff and Jasper townsites, both located in the Montane, and Village Lake Louise, located in the Lower Subalpine. Even though Jasper townsite is farthest north of the three stations, it is considerably lower in elevation, hence the warmer temperature and lower precipitation, particularly snowfall. Fig. 2 is a graphic illustration of the same data and Fig. 3 depicts climate for Banff townsite, Village Lake Louise, and Jasper townsite according to Koeppen's (Trewartha 1957) classification system. Tables 2 and 3 show variation in annual precipitation at stations recently established in Jasper and Banff. Table 4 compares short and long term data.

THE MONTANE ECOREGION

The climate of the Montane Ecoregion (Tables 2 and 3) is the warmest and driest in the two parks. Based on the Banff and Jasper townsite data (Table 1), the mean

Banff Dfb - Cold Snowy Forest Climate with no distinct dry season; cool summer.
Jasper Dfb - Cold Snowy Forest Climate with no distinct dry season; cool summer.
L. Louise Dfc - Cold Snowy Forest Climate with no distinct dry season; cool, short summer.

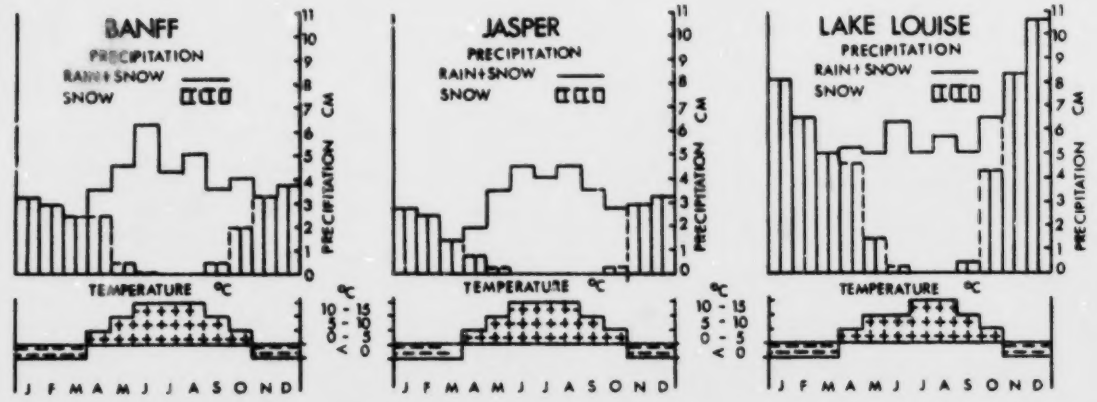

Figure 3 Classification of Banff and Jasper townsites and Village Lake Louise climates according to Koppen (1936).

D - Cold Snowy Forest Climates. Average temperature of coldest month less than -3° C (26.6° F); average temperature of warmest month more than 10° C (50° F).
f - No distinct dry season - driest month of summer more than 3 cm (1.2 inches).
b - Cool summer - average temperature of warmest month less than 22° C (71.6° F).
c - Cool, short summer - less than four months with more than 10° C (50° F).

yearly temperature is 2° to 3°C. Warm winter winds (chinooks) from Pacific air masses raise winter temperatures and the Montane Ecoregion is intermittently snow-free. In the months of December to February, Banff and Jasper townsites have about 25 days with temperatures above freezing (Janz and Storr 1977). The mean January daily temperature for Banff and Jasper townsites is approximately 4°C warmer than at Village Lake Louise, representing the Lower Subalpine (Table 1). Summer temperatures are slightly higher in the Montane than the Lower Subalpine (1.6 - 2.2°C warmer for Banff and Jasper townsites versus Village Lake Louise, Table 1). However, temperature fluctuation is probably greatest in the Montane. In the winter, temperature inversions occur when light winds permit little mixing and when cold Arctic air invades from the north. Under these conditions, the Montane Ecoregion may be colder than the adjacent Subalpine Ecoregion. Consequently, extreme minimum temperatures in the range of -50 to -54°C have been experienced in the main valleys below 1500 m elevation (Janz and Storr 1977). Extreme maxima are of the order of 38°C in valleys below 1200 m but tempera-

tures above 32°C are relatively rare (Janz and Storr 1977). These authors also point out that maximum temperatures at Banff and Jasper townsites exceed 21°C on 1 day out of 2 in July and August. Another indicator of the mild Montane climate is frequency of frost. For example, Banff townsite averages 4 days with frost for the period of June through August. In the Mount Eisenhower to Lake Louise section of the Bow River valley, this increases to 24 to 27 days for the same period (Janz and Storr 1977).

Average annual precipitation for the Montane is about 465 mm (Tables 2 and 4). Summer precipitation is slightly greater than winter precipitation (Figs 2 and 3) and the incidence of measurable summer snowfall is very low. Snowfall during the autumn is also low in some years.

Few wind records are available. As mentioned previously, the orientation of valleys contributes to wind speed and direction. Much of the Montane occurs in large valleys (the lower Athabasca, North Saskatchewan, and Bow River valleys) that are oriented approximately east-west, where they traverse the northwest-southeast trending mountain ranges. Winds in these areas are slightly stronger and more frequent than in other areas of the parks because the valleys are oriented approximately parallel to the prevailing westerlies aloft. Presently aggrading eolian deposits in the lower Athabasca and North Saskatchewan River valleys attest to this phenomenon.

THE SUBALPINE ECOREGION

The Subalpine Ecoregion occurs at elevations above the Montane Ecoregion and is cooler and moister. The mean yearly temperature is about 0°C at low elevations, based on the Village Lake Louise data (Table 1), and decreases with increasing elevation (i.e. about 0.5°C/100 m summer lapse rate). The mean annual temperature at our weather station on Mt. White, located on a north aspect in the Upper Subalpine in eastern Banff, is -1°C, based on 2½ years of data. Winter chinooks are not common in the Subalpine and snow cover is therefore continuous during winter. Janz and Storr (1977) suggest that higher elevation areas rarely have temperatures above freezing in the months of December to February. Temperature fluctuation is narrower in the Subalpine compared to the Montane. Janz and Storr (1977) indicate that although all parts of Banff and Jasper likely have had temperatures of -40°C, the occurrence of extreme minima in the -48 to -54°C range above 1500 m elevation is rare. The extreme minimum temperature at the Mt. White site, from 3 winters of data, was -37°C. Winter temperature inversions also occur in the Subalpine with valley bottoms often being colder than adjacent slopes. This sometimes produces non-forested frost hollow vegetation in valley bottoms with forests on adjacent slopes. "Red-belt", desiccation injury of coniferous trees, occurs mainly in the Subalpine Ecoregion when warm Pacific air overruns colder air. Extreme maximum temperatures are lower than in the Montane because of a decrease with elevation that is probably similar to the lapse rate of mean maximum temperature (i.e. about 0.7 - 0.8°C/100 m, Janz and Storr 1977). Data from Bow Pass (6 years record, Janz and Storr 1977) and Mt. White (2 1/2 years record) indicate extreme maximum temperatures of 28 to 29°C in the Upper Subalpine at 1850 to 1970 m elevation.

Precipitation increases with elevation and the average annual precipitation of the Upper Subalpine (763 mm) is greater than the Lower Subalpine (665 mm), based on data from a few stations (Tables 2 and 3). Winter precipitation is greater than summer precipitation (Figs. 2 and 3) and the incidence of measurable summer snowfall is greater than in the Montane. Precipitation in eastern portions of the parks appears to be lower than in western regions, based on a comparison of data from eastern (Miette Hot Springs, Willow Creek, Brazeau Warden, Rocky Forks, Cascade Lem, and Snowflake I.J.P.) versus western stations located in the Subalpine (Tables 2 and 3). This trend is supported by the extensive occurrence of dry grassland and shrubland vegetation and Cryosolic soils in eastern Subalpine regions (Achuff and Coen 1980). Conversely, Janz and Storr (1977) describe the area from Athabasca Pass to Freshfield Icefield (the Icefields area) as having an abnormally high precipitation regime relative to other areas of the parks. Snowfall, in particular, is very high. Janz and Storr (1977) suggest two factors contribute to this phenomenon. First, the Icefields area has a higher average elevation than any other area of similar size in Banff and Jasper. Secondly, a gap in the Selkirks formed by the big bend of the Columbia River lies almost due west of the Icefields area and allows passage of moist Pacific air.

Wind records for the Subalpine are scarce. Winds are generally light, although there is evidence of wide variation, related mostly to topography. Forest blowdown occurs locally and is most common in the east-west trending valleys that traverse the mountain ranges (e.g. the Snake Indian River valley between Mt. Kelsey and Willow Creek). Winds at higher elevations are stronger and more frequent as indicated by stunted and krummholz open forest occurring at the upper elevational limits of the Subalpine. The greatest effects are on exposed localities where forest may be absent. Winter observations also suggest that redistribution of snow by wind is important for the maintenance of grassland vegetation in eastern portions of the parks.

THE ALPINE ECOREGION

The Alpine Ecoregion occurs at elevations above the Subalpine Ecoregion and is the coldest in Banff and Jasper. Climatic data for Alpine areas are very few but cool mean temperatures are projected based on the trends demonstrated by a comparison of temperatures between the Montane and Subalpine Ecoregions. Additionally, the lack of forest vegetation demonstrates the rigorous climate, a significant part of which is temperature. Janz and Storr (1977) present temperature profiles based on data from various stations in Banff and Jasper and Marmot Creek basin located to the southeast of Banff. These show that as mean temperature decreases with increasing elevation, temperature range (the difference between maximum and minimum) also decreases. This trend also extends to extreme maxima and minima.

Due to the lack of climatic data, precipitation totals are uncertain. Precipitation increases with altitude from the Montane Ecoregion upward into the Alpine Ecoregion. However, somewhere in the Alpine the trend may reverse. Thus, it is difficult to generalize about Alpine precipitation. It is anticipated that trends of lower precipitation in eastern regions of the parks and heavy precipitation in the Icefields area discussed for the Subalpine Ecoregion also apply to the Alpine.

It is generally accepted that wind speed increases with elevation but there are virtually no data to quantify the relationship. Additionally, topographical influences on wind speed are greater than elevational influences. Nevertheless, Janz and Storr (1977) report that all areas above about 2300 m elevation are windy but that winds may be light in high elevation areas for several days in succession, particularly in summer. Winds are important in the Alpine. Erodible, exposed surfaces are often deflated and snow is redistributed by wind. Complex vegetation patterns in the Alpine are often linked to varying topographic exposures and resultant snow depth variability.

CLIMATIC DATA SOURCES

The following discussion gives general information on the kind and quality of climatic data available from Banff and Jasper National Parks. Data from several of these stations are presented in Tables 1, 2, 3, and 4.

FIRST ORDER STATIONS

Banff townsite records date back to 1887. The earliest records are of temperature and precipitation; later data include hourly observations of wind and sunshine. The data are representative of only the immediate area around the town. For Jasper townsite, the first order stations provide hourly observations of temperature, wind, precipitation, and humidity.

CLIMATIC STATIONS

These sources provide maximum and minimum temperatures and daily precipitation. Banff stations include Lake Louise since 1915, Anthracite from 1929-1962, and Mount Eisenhower from 1960-1971.

WARDEN STATIONS

In Banff, only a few wardens' records of any length can be located. Ski resorts such as Sunshine and Temple in Banff have some observations reported by the Warden Service. In Jasper, they are mainly temperature records, generally from thermograph charts.

STORAGE GAUGES

These data report seasonal precipitation only, as recorded by Sacramento or Fisher Porter gauges.

RESEARCH STATIONS

These data are often short term records of the elements in which a researcher is interested. Because the observations are recorded mainly during the summer and are of short duration, it is difficult to make meaningful correlations with more permanent stations. The most valuable research records are those taken by the Canadian Forestry Service and the Glaciology Division of the Geological Survey of Canada.

PHYSIOGRAPHY

W.D. Holland, G.R. Hillman, and D.T. Allan

INTRODUCTION

Banff and Jasper National Parks are situated within the Continental Ranges of the Southern Rocky Mountains which are part of the Eastern System of the Cordilleran Region of Canada (Bostock 1970). The Front and Main Ranges (Fig. 4) form the geologic subprovinces that provide structural control of the physiographic features. The mountain system is composed almost entirely of thrust faulted and occasionally folded sediments (Price and Mountjoy 1970a).

A most conspicuous feature of the Front Ranges is the linear northwest-southeast direction of the ranges and the parallel valleys that separate them. The dip of the bedrock is usually toward the southwest, thus providing long smooth slopes on this aspect. The northeast aspects are often precipitous, with broken faces and cliffs. These features are demonstrated by the photograph of Mount Rundle on the frontispiece. The Main Ranges strata, for the most part gently dipping, produce nonlinear ranges with high indi-

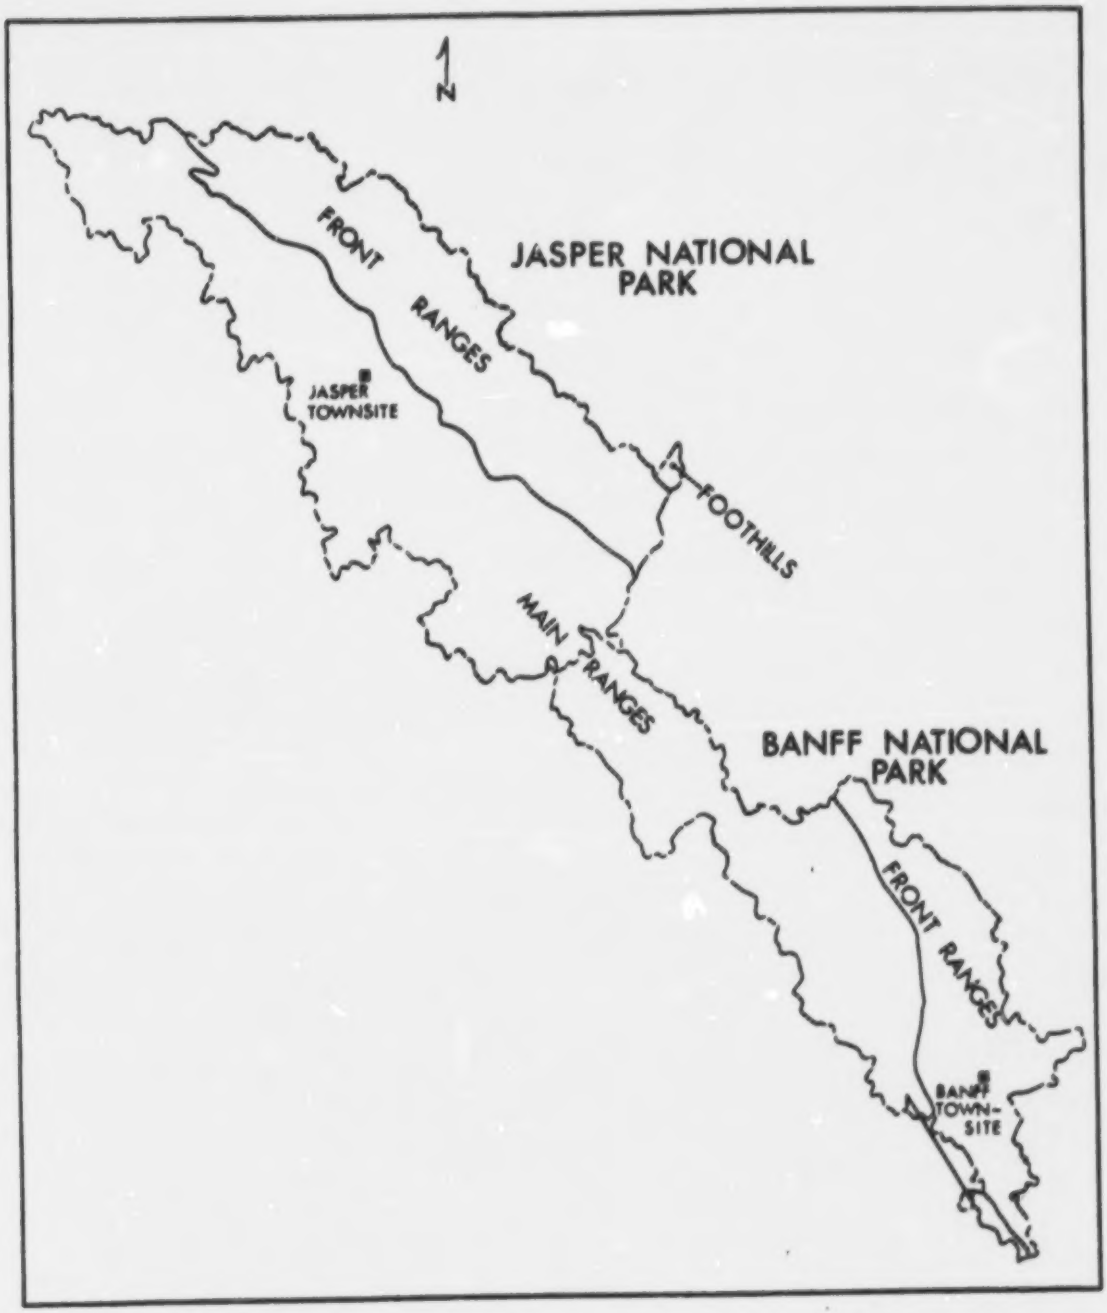

Figure 4 Geologic subprovinces of Banff and Jasper.

vidual or clustered peaks capped by resistant rock, and typify the majestic scenery for which the parks are perhaps most famous.

Elevations of the mountain tops generally increase from east to west, from a low of 2117 to 3100 m in the Front Ranges to heights of 3000 to just over 3300 m in the Main Ranges. The highest elevations occur around the Columbia Icefield, reaching from 3400 to just over 3700 m. The valley bottoms also have high elevations, the lowest being at 990 m in Jasper near Brule Lake and 1330 m where the Bow River leaves Banff. The main valley bottoms commonly have elevations between 1200 and 1500 m. The effect of high elevation on precipitation, temperature, and topography result in the parks being a

headwaters area for some of Canada's larger rivers. The main valleys of the Bow, Athabasca and North Saskatchewan rivers are the largest in the parks and, though they are to some extent parallel to the northwest-southeast direction of the mountain ranges, they do eventually cut across the ranges allowing drainage flow onto the Alberta plains to the east and north. A number of smaller rivers are also transverse to the mountain ranges, namely the Panther, Red Deer, and Clearwater Rivers in Banff, and the Brazeau, Southesk, and Smoky in Jasper. Otherwise, the rivers and their tributaries exhibit a definite trellis drainage pattern.

DRAINAGE AND HYDROLOGY

Banff and Jasper National Parks play an important role in supplying water to residents and tourists in the parks and, more particularly, to downstream users. Total annual runoff from the area ranges from about 380 mm near the eastern boundaries to over 1000 mm near the Continental Divide (Neill et al. 1970). This compares with minimum mean annual precipitation of about 380 to 500 mm in the main river valleys, and maximum of over 1250 mm near the Divide (Janz and Storr 1977). Reports for adjacent mountainous areas east and south of the Parks indicate that mean annual runoff may exceed 60% of mean annual precipitation, but for many streams the average annual water yield is between 40 and 50% of mean annual precipitation (Eastern Rockies Forest Conservation Board 1963-71, Hanson n.d.).

The rivers that issue from Banff and Jasper are fed by the extensive ice and snow-fields that persist year-round at high elevations. Records for several hydrometric stations maintained within and adjacent to the parks (Water Survey of Canada 1910-1979, Water Survey of Canada 1980) are widely used in flood frequency analyses and to describe streamflow characteristics (Neill et al. 1970, Kellerhals et al. 1972, Stolte and Dumontier 1977, F.F. Slaney and Company Limited 1978, Golder Associates 1981). They indicate that about 70% of the total annual flow occurs during the months June through August. Peak discharges are usually reached in June or July (Fig. 5).

Stream courses are strongly controlled by topography. In Banff and Jasper they may be characterized by some or all of the following features: steep gradients, waterfalls, rapids, gorges, canyon walls, and coarse bed materials. Rivers, such as the Chaba, Sunwapta, and the upper headwaters of the Athabasca, which flow through flat-bottomed valleys, deposit glaciofluvial materials on the valley floor. This deposition has produced extensive braided stream systems in these valleys.

Stream gradients reported in the literature (Kellerhals et al. 1972, Donald et al. 1977, F.F. Slaney and Company Limited 1978, and Golder Associates 1981) reflect the position of the stream channel reach relative to the main valley floor. Mountain Creek (gradient: 80 m/km) and Sulphur Creek (71 m/km), for example, drain steep mountain terrain and flow into larger streams with gentler gradients. Sulphur Creek joins the Fiddle River which has an average gradient of 17 m/km. Gradients of 19 and 15 m/km have been reported for Forty Mile Creek and the Pipestone River near Lake Louise, respectively. In contrast, the Bow River which flows through a main valley, has a gradient of 0.13 m/km at Banff. The gradient of the Athabasca River at Jasper is 3 m/km.

Banff National Park is drained entirely by the Saskatchewan River system (Fig. 6), the primary source of water for the Great Plains region of Alberta and Saskatchewan. Although mountains comprise only ⅛ of the total drainage area, Banff, Jasper, and Waterton Lakes National Parks and the adjacent Rocky Mountains Forest Reserve supply ⅓ of the total annual flow of the Saskatchewan River system (Hanson n.d.) From northern Banff, the North Saskatchewan River is fed by the Alexandra, Howse, Mistaya, Siffleur, and Clearwater Rivers. Other large rivers such as the Red Deer, Panther, Bow, Pipestone, and Cascade are part of the South Saskatchewan River system.

Jasper National Park is drained primarily by the Athabasca River system. The major rivers tributary to the Athabasca River within the park include the Snake Indian, Snaring, Miette, Rocky, Chaba, Sunwapta, Maligne, and Whirlpool Rivers. The Brazeau River forms the southeast boundary of the park and drains into the North Saskatchewan River. The northwestern portion of the park is drained by the Smoky River which is part of the Peace River system (Fig. 6).

A recent floodplain study of the Bow River at Banff townsite (Beckstead 1980) indicated that the 100-year flood (40b m^3/s) will cause major flooding in the recreation grounds south of the Bow River and upstream from the Banff Avenue Bridge. Flooding has been reported on 11 occasions since 1894. In each case maximum daily discharge exceeded 283 m^3/s (1000 ft^3/s). The record maximum daily discharge (377 m^3/s) occurred 15 June, 1923. Floods of this magnitude are usually accompanied by road and rail track washouts and the destruction of bridges on tributary streams such as the Spray River. The estimated 100-year flood for many stations in Banff and Jasper National Parks, and in the adjacent areas of Alberta are given in Stolte and Dumontier (1977) and in Golder Associates (1981).

Jasper townsite is situated high enough above

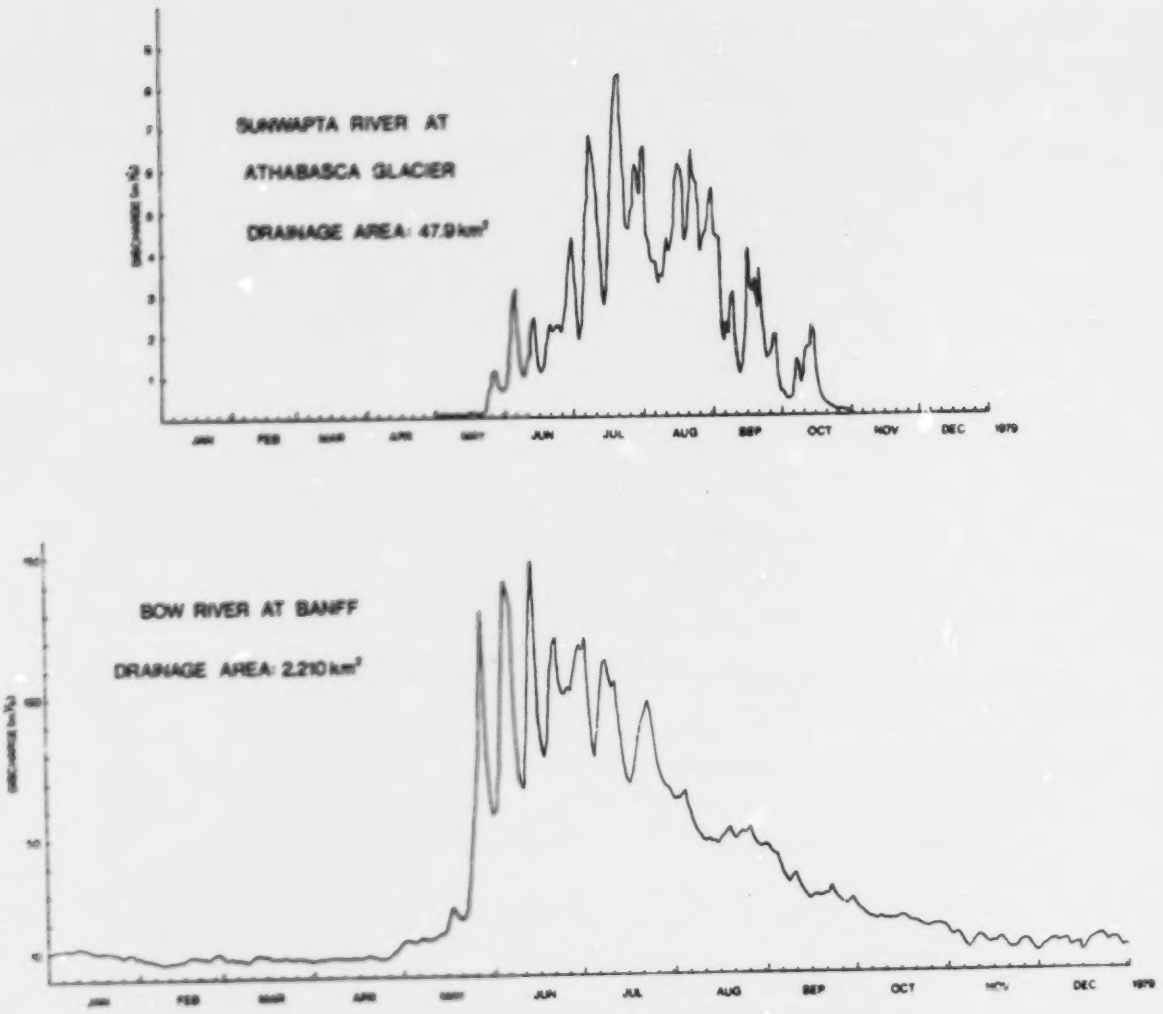

Figure 5 Hydrographs showing dominance of summer flows for streams in Banff and Jasper National Parks. (from data supplied by the Water Survey of Canada).

the Athabasca River that there is less risk of the town being flooded by the river than by upslope runoff from intense rainstorms. During extreme flood conditions the Athabasca River will extend into the low-lying areas in the vicinity of Beauvert Lake and Mildred Lake.

Intense 24-hour rainstorms in excess of 50 mm, and of the 'cold low' type have been recorded at Jasper townsite on three occasions: August 5, 1969 (108 mm), July 1, 1935 (86 mm), and May 22, 1944 (70 mm) (Janz and Storr 1977). The storm of August 5, 1969 caused extensive rock slides along the highway between the townsite and the east gate of the park. Railroad tracks were washed out and streams in the Jasper area became torrents (Janz and Storr 1977).

A 'cold low' was also responsible for the spectacular once in hundred years flood on the Smoky River drainage in June 1972 (Warner and Thompson 1974). The Alberta Resource Railway together with the towns of Grande Prairie, Grande Cache, and Peace River were all affected by the flood. Together they sustained losses in excess of $8 million. Although the Smoky River rises in Jasper National Park, the centre of the storm (200 mm isohyet) was located at Nose Mountain, well to the north of Jasper. Precipitation for the same storm in Jasper was about 50 to 75 mm.

The hydroelectric power potential of the Bow River drainage was investigated early in Banff's history (Hendry 1914). Development of the Cascade River for power production

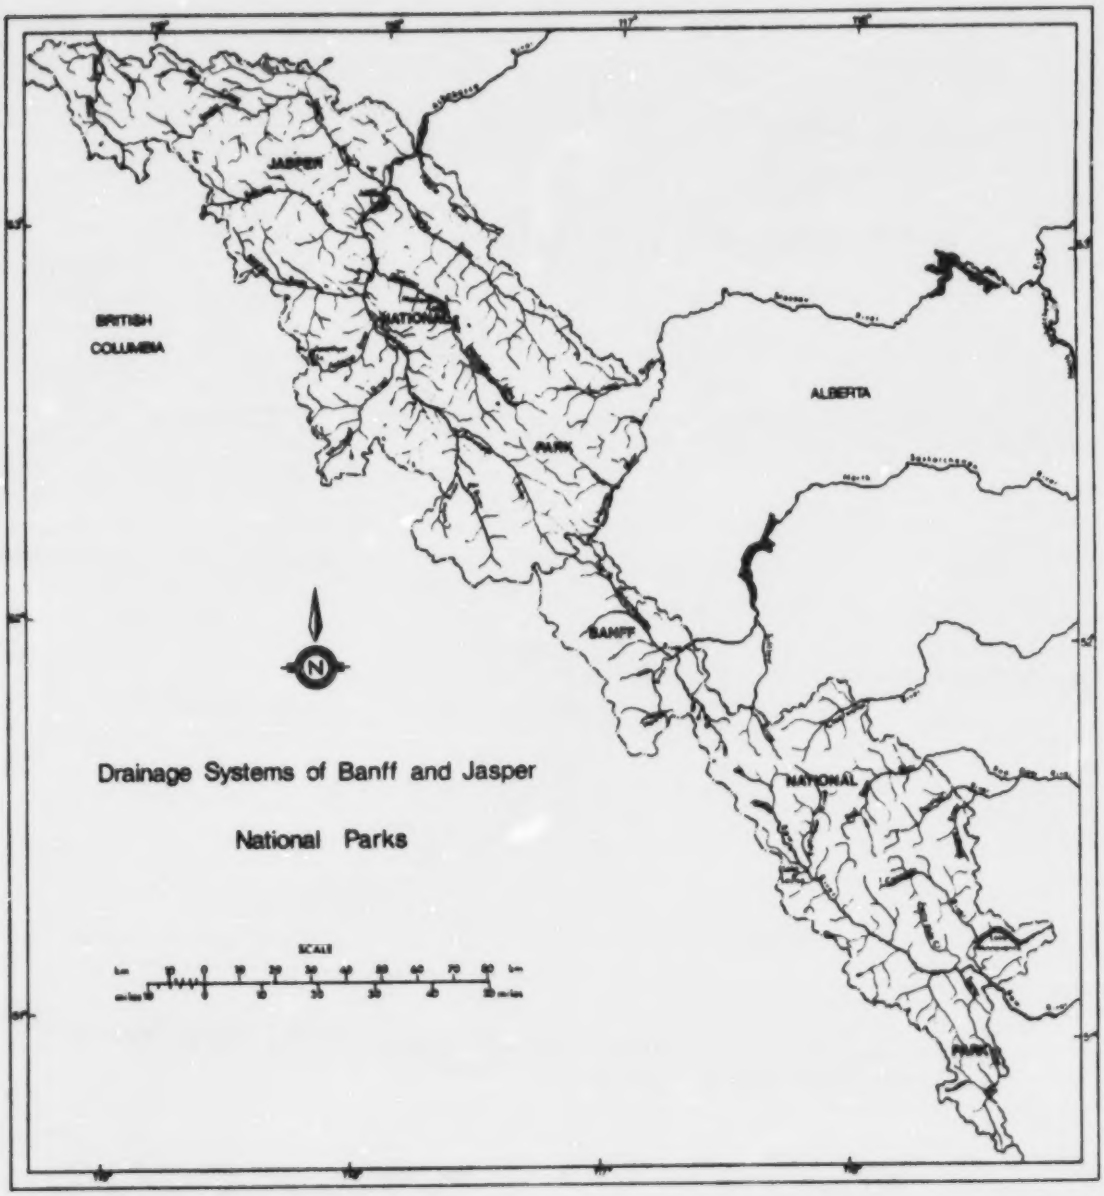

Figure 6 Drainage systems of Banff and Jasper National Parks.

created Lake Minnewanka as the largest lake in Banff. It has a surface area of 1295 ha, a maximum depth of 80 m, and occurs at an altitude of 1454 m. The next largest lakes are Hector (altitude:1737 m, area:688 ha), Bow (1981 m, 364 ha) and Peyto (1865 m, 194 ha) (Rawson 1939). Regardless of size, however, most of the lakes in Banff are important for recreation purposes.

Lakes in Banff and Jasper were formed in several ways. Some are dammed by landslides e.g. Moraine Lake, or by the moraine left by retreating glaciers e.g. Lake Louise and Amethyst Lake. Many result from damming by fans of tributaries where they join main streams in a valley bottom with a gentle gradient. Jasper Lake is presently dammed by fans of the Snake Indian and Rocky Rivers. Baird (1963) considers this to be a remnant of a former, much larger lake. Still others are formed in depressions either gouged out of bedrock or in stagnant ice moraine kettles.

Reports describing limnological studies (Ander-

son and Donald 1978, Donald and Anderson 1978) provide data on some of Jasper's larger lakes. Maligne Lake situated at an altitude of 1675 m, with surface area of 2066 ha and maximum depth of 96 m is the largest lake in the park. Other large lakes include Jasper (altitude: 10[illegible] m, area: 1085 ha), Amethyst (1967 m, [illegible] ha), Medicine (1442 m, 516 ha), Brazeau, and Twintree.

Medicine Lake is a karst lake which feeds an underground cave capable of transporting up to 57 m^3/s of water 17 km down-valley in 20 h (Brown 1973). During very high flows, usually mid-summer, Medicine Lake spills into the Lower Maligne River system directly. Later, however, as the water supply from melting snow diminishes, the lake shrinks and the Maligne River near the exit from Medicine Lake becomes a dry streambed. Flow at this time is entirely underground; by November the lake is almost completely drained (Baird 1963).

Hot springs located in the parks are important tourist attractions. The Cave and Basin Hot springs and the Upper Hot Springs are situated near Banff. Miette Hot Springs is located near the east entrance to Jasper National Park. The springs originate from rain, snow, and surface water that has seeped into fractures or pores in the rock and circulated to depths where the temperature of the rock is high. Part of the water is returned to the surface along fracture zones. On its way it mixes with various amounts of cool surface water resulting in hot springs of various temperatures (Baird 1963, Belyea 1964). Discovery of the Cave and Basin springs in 1883 led to designation of the area as Canada's first National Park (Belyea 1964).

SURFACE EXPRESSION

The main physiographic features of Banff and Jasper are subject to marked control by mountain building processes with stratified sedimentary rock. In addition, the landscape has been modified by extensive Pleistocene glaciation and post-glacial erosion and deposition. Vestiges of the former glaciation are visible in the small glaciers that remain at high elevations, mostly near the Continental Divide (Falconer et al. 1966). These retreating glaciers are still actively altering the landscape. Surface features resulting from the earlier glaciation are horns, arêtes, cols, cirques, truncated spurs, tarns, hanging valleys, and U-shaped valleys (Harrison 1976). Other glacial features are numerous morainal, glaciofluvial, and glaciolacustrine deposits. Eolian, fluvial, and colluvial postglacial processes have also modified the landscape. These glacial and postglacial features are further described under the geomorphology section, Ecosite descriptions, and the legend.

PHYSIOGRAPHY AND PEOPLE

The significance of the physiographic features is in their impact on the physical, chemical, and biological processes that form the environment of Banff and Jasper, and how these features affect land use in the parks. Self-evident relationships include: 1)amenable climatic and topographic combinations that make the Montane Ecoregion subject to the most intensive land use in Banff and Jasper; 2)the direction of the Athabasca and Bow River valleys, leading to the Yellowhead and Kicking Horse Passes respectively, and providing national transportation corridors with attendant land use pressures from highways, railways, oil lines, power lines, and service centres; and 3)the flat-lying structure and direction of the Main Ranges, which combined with the influence of aspect on glaciation, locate many of the lakes in cirque positions on the east side of individual ranges thus attracting people to these sites; e.g. the Ten Peaks area near Moraine Lake—Larch Valley in Banff, and the Ramparts of the Tonquin Valley in Jasper. The remainder of the report describes and locates natural resources, and may be referred to for a more detailed account of physiographic features.

GEOLOGY

W.S. Taylor

REGIONAL SETTING

Banff and Jasper lie in the southern portion of the Rocky Mountain Thrust Belt, the southeasterly most sector of the geological region known in Canada as the Cordilleran Orogen. This is part of a circum-Pacific orogenic belt that is generally some 800 km wide. Development of the Cordilleran Orogen is a result of the evolution of the Cordilleran Geosyncline from mid-Proterozoic to Recent time. At present the region is tectonically quiet (Douglas et al. 1970).

STRATIGRAPHIC FRAMEWORK

Broad trends of the depositional basin history are outlined by Douglas et al. (1970) and Price and Mountjoy (1970a). Geologic strata from late Proterozoic to early Mesozoic are represented in Banff and Jasper, as recorded in two separate stratigraphic sequences. The older, ranging in age from Hadrynian to Late Jurassic, represents a slowly subsiding miogeosyncline—shelf marine sequence. Sediments may be divided into detrital material (allogenic) derived from the North American craton to the northeast, and shallow water carbonates (authigenic). The second sequence, a clastic wedge, is non-marine and of Late Jurassic and Early Cretaceous age within the

parks. The rising Cordillera in the Columbian Orogen to the southwest was the probable source of these sediments (allogenic).

In general, purely allogenic sediments were devoid of carbonate, and became noncalcareous clastic rock (e.g. quartz sandstone, shale). While some chert and evaporites occur, authigenic minerals were principally carbonate, and became carbonate bedrock (e.g. limestone, dolostone). Mixtures of both were common, and are referred to as calcareous clastic (e.g. calcareous siltstone, argillaceous limestone).

Bedrock derived from the consolidation of these sediments has been systematically described and classified into rock-stratigraphic (lithology dependent) units (McLaren and Mountjoy 1962, Mountjoy 1962, 1964, 1965, Irish 1965, Norris 1965, Aitken and Norford 1967, Charlesworth et al. 1967, Gibson 1968a, 1968b, 1974, MacKenzie 1969, Cook 1975, Pugh 1975, McLean 1977, and many others). Much of this work has been summarized by Douglas et al. (1970). A schematic, generalized stratigraphic column for Banff and Jasper is compiled from Price and Mountjoy 1970a, b, 1978b, Jackson 1975, and Mountjoy 1980 (Fig. 7). For purposes of this report lithologies of these Groups and Formations are generalized into three categories:

1. noncalcareous, medium and coarse grained clastic,
2. noncalcareous, medium and fine grained clastic, and
3. carbonate and calcareous clastic.

STRATIGRAPHIC FRAMEWORK AND ECOLOGICAL LAND CLASSIFICATION

There is often a close relationship between the characteristics of surficial sediments and the source bedrock (Rutter 1972, Stalker 1973). More specifically, the three generalized bedrock lithology categories correlate with the three calcareousness and textural groups of unsorted genetic materials important in Banff and Jasper (Table 5).

Thus, there is an inferred link between the named rock-stratigraphic Groups and Formations (Figure 7) and ecosites described in this report, especially those on residual, colluvial and morainal genetic materials. Where these materials are noncalcareous and coarse textured, they are derived from any of the Gog Group, less commonly the Ishbel Group, or Mount Wilson, Misty (within Rocky Mountain Group), or Cadomin Formations. If the genetic materials are noncalcareous and medium textured, they are likely derived from the Miette or Fernie Groups, the Kootenay, Nikanassin or Luscar Formations, or less commonly part of the Arctomys Formation. The balance of the Groups and Formations produce calcareous, medium textured unsorted sediments(Table 5).

STRUCTURAL FRAMEWORK

The broad structural and tectonic elements of the Rocky Mountain Thrust Belt are outlined by Douglas et al. (1970) and discussed more specifically by Price and Mountjoy (1970a). The portion of this belt containing Banff and Jasper was produced by the Laramide Orogeny over the period from late Upper Cretaceous to mid-Tertiary (Oligocene). Sediment deformation is of the decollement (independent of crystalline basement rock) type, with little or no metamorphism, volcanism, or plutonism. One diabase dyke occurs near Bow Lake in Banff (Price and Mountjoy 1978a). Some sediments of the early miogeosyncline have undergone low-grade metamorphism. Dominant structural features are discrete, discontinuous, interleaved, and overlapping thrust faults. The thrust sheets typical of the Rocky Mountains were northeasterly foreshortened along these faults and are now stacked on the flank of the North American craton.

The present degree of erosion subsequent to orogeny has resulted in a series of subparallel, northwest-southeast trending geological subprovinces separated on the basis of their distinctive stratigraphy, structure, and topography. Boundaries often correspond to fault traces, but these are not necessarily contiguous. From east to west these subprovinces are the Foothills, Front Ranges, Main Ranges, and Western Ranges.

The Western Ranges subprovince does not occur in Banff or Jasper. While opinion

Table 5 Correlation of generalized bedrock lithology with calcareousness and texture groups of unsorted genetic materials.

Generalized Bedrock Lithology	Calcareousness and Texture of Unsorted Genetic Material
Noncalcareous, medium and coarse grained, clastic	Noncalcareous, coarse textured
Noncalcareous, medium and fine grained, clastic	Noncalcareous, medium textured
Carbonate and/or calcareous clastic	Calcareous, medium textured

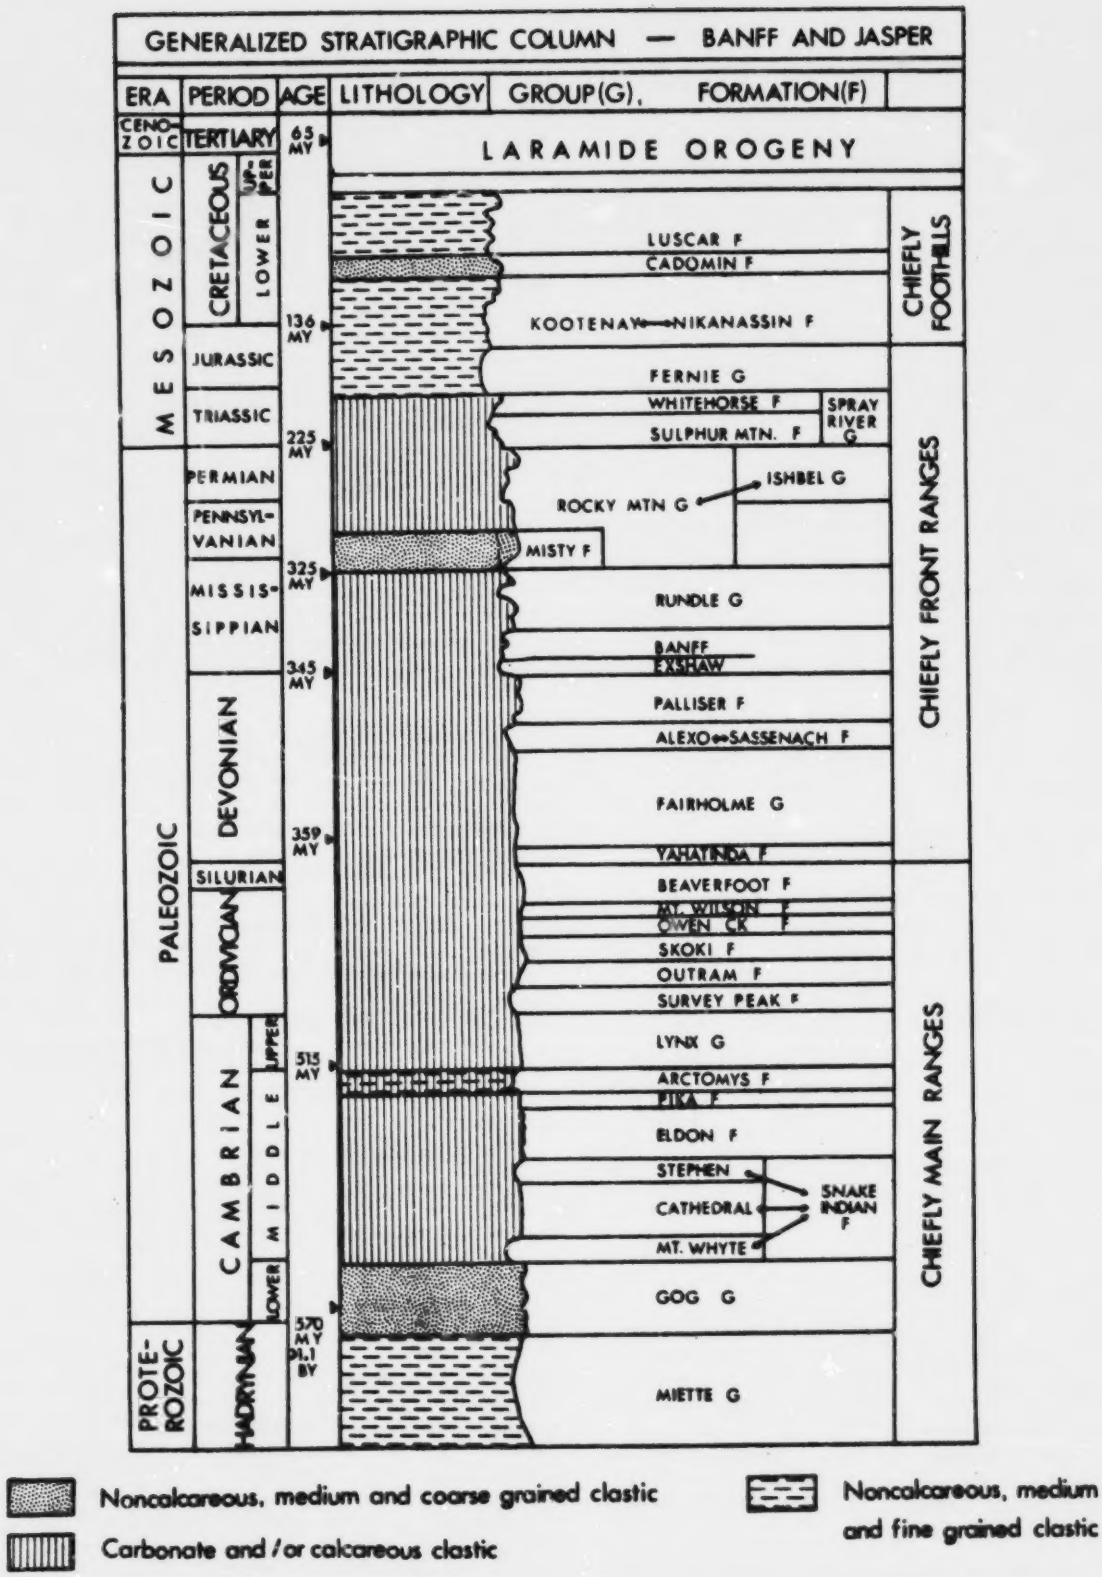

Figure 7 Generalized time scale and stratigraphic column for Banff and Jasper.

varies, especially about Jasper's eastern boundary from Rock Creek south to the Brazeau River (Lang 1947, Mountjoy 1964, Irish 1965, Gibson 1968a, Price and Mountjoy 1970a, Pugh 1975), the consensus is that, except for a small triangular peninsula between the Southesk and Brazeau Rivers, the Foothills subprovince also is effectively excluded from the parks. However, Foothills characteristics occur locally within the eastern side of both parks where topography is subdued (forested plateaus and rounded ridges) and bedrock is comprised of the previously mentioned Mesozoic clastic wedge sediments.

The Front Ranges subprovince is regionally recognized by the dominant exposure of steeply southwest dipping Devonian to Jurassic rocks. These are arranged in rugged subparallel ridges of resistant Paleozoic carbonate peaks separated by valleys carved from the less resistant Mesozoic clastic rocks.

The relative flatness of the thrust plates in the Main Ranges subprovince results in beds that are gently dipping, with broad and open folds. Erosion has carved mountain ranges that are far less linear than the Front Ranges into the more competent pre-Devonian sequence that is characteristic of the Main Ranges. Typically, mountains are capped by resistant Paleozoic carbonates and grade downwards in both time and elevation to valley walls composed of the earlier clastic sediments of the miogeosyncline, deposited in the late Hadrynian and early Cambrian.

Fig. 4 sketches the distribution of the Foothills, Front Ranges, and Main Ranges in Banff and Jasper as compiled from Douglas (1969), Price and Mountjoy (1970a), Green (1972), Cook (1975), Jackson (1975), Pugh (1975), and Mountjoy (1980). Interpretation is least reliable in extreme southern Banff.

STRUCTURAL FRAMEWORK AND ECOLOGICAL LAND CLASSIFICATION

The structural framework gives information about distribution of the named bedrock units within the parks through the vehicle of subprovince. Formations and Groups typical of each of the Foothills and Front and Main Ranges are indicated in Fig. 7. The link between these rock-stratigraphic units and the Ecosites of this Ecological Land Classification is discussed earlier. The addition of structural information (via location) allows a closer correlation of these Ecosites to specific bedrock. As an example, the source strata for an Ecosite mapped on noncalcareous, medium textured glacial till located in the Main Ranges were probably of the Miette Group (Figs. 7,4, Table 5).

Distribution of Groups and Formations, as shown on geological maps, is strongly correlated with Ecosite distribution, especially those occurring on unsorted genetic materials with a restricted bedrock source. Geological maps complementing this Ecological Land Classification to which the reader is referred, are by Price and Mountjoy (no date), Mountjoy (1960, 1964), Price and Mountjoy (1970a,b, 1971a,b, 1972a,b), Cook (1975), Price et al. (1978, 1979), and Mountjoy (1980).

Several other positive correlations between this study and bedrock geology are noted throughout the text of this report.

GEOMORPHOLOGY

B.D. Walker, D.T. Allan, and W.S.Taylor

INTRODUCTION

Soil and vegetation development is influenced by landform. Landform consists of genetic material, surface expression, and modifying processes (C.S.S.C. 1978b). This section describes characteristics of landform relevant to Ecological Land Classification in Banff and Jasper.

Genetic material is most important because it provides the framework within which to classify and interpret other properties of the landscape. Consequently, genetic materials are emphasized in the following descriptions. Surface expression describes landscape form but is often dependent upon genetic material (i.e. mode of deposition). Modifying processes occasionally influence landscape form but are more important in aiding classification and interpretation of other landscape properties, particularly soils and vegetation. Some processes are genetic material specific. Both surface expression and modifying processes are discussed under the genetic material descriptions following.

LANDFORM CLASSIFICATION

Landform classification follows, with modification, the system outlined by C.S.S.C. (1978b). Reimchen and Bayrock (1975) mapped and described, for Banff and Jasper, similar groups of genetic materials using a terrain analysis system patterned on that of Fulton et al. (1974). Genetic materials are organized into four groups (components), namely consolidated (bedrock), unconsolidated mineral, organic, and ice. The bedrock and ice components lack soil and vegetation and are not further subdivided. The organic component is of limited areal extent and thinly mantles unconsolidated mineral deposits. Because most soil and vegetation in Banff and Jasper occur on the unconsolidated mineral group it is therefore emphasized in the following discussion.

The unconsolidated mineral group is subdivided according to mode of formation or deposition. Ten genetic material classes (modified from C.S.S.C. 1978b) are recognized. These are listed in Table 6 in order of increasing source diversity, increasing influence on properties by depositional agents, and decreasing bedrock lithology influence. Residual material (R^U—Rock, modified by the qualifying descriptor Unconsolidated) is similar to saprolite as defined by C.S.S.C. (1978b) except for grain size properties and kind of weathering. Landslide material (C^A—Colluvium, modified by the qualifying descriptor Avalanched) is a subset of colluvial material, as defined by C.S.S.C. (1978b), herein differentiated to accomodate cataclysmic colluvial processes. The ice contact stratified drift (MF^G—Moraine and Glaciofluvial) class, undefined by C.S.S.C., accomodates polygenetic, stratified glacial drift, its components being inseparable at the 1:50,000 map scale. Fluviolacustrine material (F^L— Fluvial material modified by the qualifying descriptor Lacustrine) fits neither the fluvial nor lacustrine classes defined by C.S.S.C. (1978b) and encompasses sediments deposited in low energy fluvial environments.

Genetic material classes are further subdivided according to textural and chemical (calcareousness) properites imparted either by source area lithology or modified by the depositional media. Twenty genetic material units, listed in Table 6, are defined specifically for the Banff - Jasper Ecological Land Classification. To organize textural variability for convenience of presentation, the textural classes defined by C.S.S.C. (1978a) are grouped into coarse, medium, fine, coarse textured and stratified, fine textured and stratified, and variable categories. Each group is defined specifically for the genetic material unit to which it applies. Similarly, the calcareousness classes defined by C.S.S.C. (1978a) are generalized into three major groups: noncalcareous, calcareous, and altered. The first two are defined specifically, in terms of $CaCO_3$ equivalent and reaction (pH), for the genetic material units to which they apply. The altered group encompasses materials in the weathering (pedogenic) zone; consequently, original calcareousness and reaction are unknown. Occasionally, a variable calcareous group is used to combine calcareous and noncalcareous materials at the study scale.

RESIDUAL GENETIC MATERIAL

Residual material in Banff and Jasper is physically and chemically weathered bedrock and is designated by the landform symbol "R^U". It is similar to saprolite (C.S.S.C. 1978b) in that the present texture is a relic of the chemically altered rock. However, particle sizes beyond silt and clay are included in Banff and Jasper. Secondly, physical weathering of highly jointed bedrock results in material that is neither coherent nor has original grain relationships maintained. Thirdly, R^U includes failed bedrock that retains some original bedding structure and, though extremely jointed and somewhat displaced, is nonfragmental.

Residuum is produced by frost activity along jointing (joint-block separation). The resulting increased surface area is then subject to weathering of the cement holding grains of the rock together. This process is still active on most residual material in the parks.

Residual material is derived from recessive bedrock; factors that make bedrock recessive also make it residuum-producing. These include relative softness, laminated bedding, low degree of cementation, weatherable cement, and others. Most residual material in the parks is medium textured, derived from medium and fine grained clastic rock, either calcareous or noncalcareous. Structural setting is also important. Strata in the Front Ranges were generally less competent during orogeny than those in the Main Ranges (Price and Mountjoy 1970a), the greater weakness and deformation in the Front Ranges generating extensive areas of highly jointed bedrock.

Elevation and topography influence residual material distribution. In the Montane, residuum is scarce, and in the Subalpine rare and expressed mainly as postglacial failed bedrock, because glacial and more recent unconsolidated materials cover nearly all of the in situ recessive rock. This occurs despite the carving of valleys, especially in the Front Ranges from this potentially residuum-producing rock (Price and Mountjoy 1970a). However, in the Alpine, residuum is best expressed. Plate 1 shows an Alpine landscape of this material on Copper Mountain in Banff. The area was glaciated, as indicated by an erratic, but the material covering the landscape has originated almost exclusively through weathering. Stalker (1973) and Harrison (1976) report that some high elevation areas in the Rockies escaped glaciation. Though inconclusive, the presence of well developed soils and well established vegetation on some Alpine residuum versus incipient, unvegetated Regosols on other apparently comparable sites suggests some of the former escaped glaciation (cf Plates 1 and 126).

Residuum on high broad plateaus and in lower passes that have been glaciated is sometimes locally mixed with till. Altered medium textured eolian material (Eolian material B) may mantle or be mixed with it as well.

As previously discussed, textures are medium and controlled by lithology. However, a con-

† Modified from C.S.S.C. (1978b) as outlined under Landform Classification in this section.

tinuum of chemical properties from noncalcareous, acid, to highly calcareous, alkaline exist. For purposes of this Ecological Land Classification, this continuum was broken into two genetic material units. These are Residuum A (essentially noncalcareous) and Residuum B (calcareous), with characteristics as discussed below.

RESIDUUM A

Concept and Distribution

Residuum A is noncalcareous, medium textured material derived by the in situ physical and chemical weathering of noncalcareous, medium to fine grained clastic bedrock. Residuum A is the dominant residuum in the Main Ranges. There, Miette Group strata produce most of this residual material mapped in Ecosites. However, Residuum A from recessive bedrock of the Main Ranges' upper stratigraphic column (e.g. Arctomys Formation) is sometimes included in the Miscellaneous Landscape Colluvial Rubble (CR) on gentle slopes. In the Front Ranges, medium grained bedrock of the Fernie Group and younger produces Residuum A (Fig. 7). Other aspects of distribution have been previously discussed.

Surface Expression and Modifying Processes

Most surfaces of Residuum A are inclined, hummocky, or ridged. Inclined examples are usually convex, some to the point of being dome-like on broad mountain ridges. These indicate homogeneous bedrock, or that a uniform bed of the residuum-producing bedrock conforms closely to the ground surface. Hummocky expression is usually associated with postglacial failure of bedrock and is proportionately more common in the Subalpine. Ridged expresssion indicates that surfaces truncate differing strata where beds dip at an angle relative to the surface.

Slopes are mostly complex, and range up to 45%. Material on the steeper of these is transitional to colluvium as gravity induced movement becomes evident, especially by solifluction in the Alpine. Cryoturbation is also common in the Alpine on this material.

Textural Properties

Residuum A is normally medium textured, with sand content ranging from 20 to 60%, clay from 5 to 20%. These values occupy part of the silt loam, loam, and sandy loam textural classes of C.S.S.C. (1978a).

Content of fine earth decreases and coarse fragment content increases with depth in sola developed on Residuum A. Coarse fragment content ranges from 50 to 90% by volume in lowest least altered horizons. Fragments are angular gravelly and cobbly as defined by C.S.S.C. (1978a) when derived from siltstone and sandstone, but are more often channery or slaty from the Miette Group and shaly from Mesozoic strata. Fragments of these latter three categories are often breakable with hand force. Sample preparation therefore can strongly influence grain size determinations.

Calcareousness and Reaction Properties

Residuum A is usually noncalcareous, hence acid, ranging from extremely to medium acid (C.S.S.C. 1978a) with pH values between 4.5 to 6.0. In the low lime phase transitional to Residuum B, separation of these materials is based on pH of the sola developed on them. Specifically, Residuum A produces sola with pH $\leq$5.5 to a depth of 25 cm below the top of the B horizon. This ranges up to about 5% $CaCO_3$ equivalent.

Discussion

Residuum A is the principal genetic material of the Copper (CP) Ecosection, and is a common constituent of the Brazeau (BZ) Ecosection and the Heather 1 (HE1) Ecosite. It is an occasional constituent of the CR Miscellaneous Landscape as discussed earlier (e.g. between upper Dolomite Creek and the Mistaya River in Banff).

Residuum A is separated from colluvium by the steep topography and generally fragmental nature of the latter. Till has diverse lithology, is more compacted, and is lower in coarse fragment content. Residuum B is the calcareous counterpart of Residuum A.

RESIDUUM B

Concept and Distribution

Residuum B is calcareous, medium textured material derived from the in situ physical and chemical weathering of calcareous clastic bedrock. Residuum B is primarily distributed in the Front Ranges. There the Spray River Group is the principal bedrock source. Most Residuum B is mapped in Ecosites. However, some is included in the Miscellaneous Landscape Colluvial Rubble (CR) often on gentle slopes on recessive bedrock in the Main Ranges upper stratigraphic column.

Surface Expression and Modifying Processes

Most surfaces of Residuum B are inclined, hummocky, or ridged. Inclined examples are usually convex, some to the point of being dome-like on broad mountain ridges. These indicate homogeneous bedrock or that a uniform bed of the residuum-producing bedrock conforms closely to the ground surface. Hummocky expression is usually associated

with postglacial failure of bedrock and is proportionately more common in the Subalpine. Ridged expression indicates that surfaces truncate differing strata where beds dip at an angle relative to the surface.

Slopes are mostly complex, and range up to 45%. Material on the steeper of these slopes is transitional to colluvium as gravity induced movement becomes evident, especially by solifluction in the Alpine. Cryoturbation is also common in the Alpine on this material.

Textural Properties

Residuum B is normally medium textured, with sand content ranging from 20 to 60%, clay from 5 to 20%. These values occupy part of the silt loam, loam, and sandy loam textural classes of C.S.S.C. (1978a).

Content of fine earth decreases and coarse fragment content increases with depth in sola developed on Residuum B. Coarse fragment content ranges from 50 to 90% by volume in lowest, least altered horizons. Fragments are most frequently angular gravelly and cobbly as defined by C.S.S.C. (1978a), but some channery, shaly, and flaggy examples occur. Fragments are generally coherent and resist breakage, except for shaly material.

Calcareousness and Reaction Properties

Residuum B is usually calcareous, hence neutral to moderately alkaline in reaction. Calcium carbonate equivalent is inferred to be generally <35% with pH ranging from 7.0 to 8.0. In the low lime phase transitional to Residuum A, separation of these materials is based on pH of the sola developed on them. Specifically, Residuum B produces sola with pH >5.5 to a depth of 25 cm below the top of the B horizon. This ranges down to about 5% $CaCO_3$ equivalent.

Discussion

Residuum B is a common constituent of the Brazeau (BZ) Ecosection and the Heather 1 (HE1) Ecosite. It is occasionally a constituent of the CR Miscellaneous Landscape as discussed earlier (e.g. between upper Dolomite Creek and the Mistaya River in Banff).

Residuum B is separated from colluvium by the steep topography and generally fragmental nature of the latter. Till has diverse lithology, is more compacted and is lower in coarse fragment content. Residuum A is the non-calcareous counterpart of Residuum B.

LANDSLIDE GENETIC MATERIAL

Landslide genetic material in Banff and Jasper is the deposit generated following rapid, gravity-induced movement of mineral material downslope en masse. C.S.S.C. (1978b) includes this process in the definition of avalanche and considers the material to be colluvial. Thus, as used in this report the terms landslide and colluvial avalanche ($C^{\wedge}$) are synonymous. An outline of the scope of the term landslide is given by Gary et al. (1972).

Landslides are sporadically distributed throughout the parks. Usually they were derived from failed bedrock of various lithologies,but occcasionally they originated from preexisting unconsolidated mineral material (e.g. mid-Dolomite Creek valley in Banff). Thus, most unaltered landslide material contains little fine earth, a feature that strongly influences initial soil and vegetation development. Because of the unreliability of lithology interpretation in material derived from a specific local source, limited occurrence, and the controlling influence of coarse fragment content, landslide material was not further subdivided.

LANDSLIDE MATERIAL

Coarse Fragments

Coarse fragments comprise 50 to 100% of the material by volume in landslide deposits. Slides generated from massive, resistant bedrock have blocky coarse fragments (angular fragments >256 mm), occasionally as large as house-sized. Those from highly jointed recessive bedrock are often mixed rubbly (angular fragments <256 mm) and blocky, and have more fine earth associated with them. Soil and vegetation develop more rapidly on the finer grained slides, while coarsest portions often continue to have sparse soil and vegetation regardless of age. Much of the fine earth fraction in soils on older slides is altered medium textured eolian material (Eolian material B). Sola developed on landslide material from failed bedrock are generally fragmental at depth. Surfaces are often exceedingly to excessively stony.

Fine Earths

Calcareousness properties of landslide material range from non- to extremely calcareous, and both extremes may occur within one slide derived from contrasting materials. Textures, where fine earths occur, are variable from medium to coarse, spanning silt loam, loam, sandy loam, and loamy sand as defined by C.S.S.C. (1978a). Fig. 8 illustrates textural variation among selected C horizons of pedons sampled on landslide material. Exclusive of eolian addition to surfaces, textures often reflect the nature of material prior to failure, as landslide events in themselves do not greatly modify texture. Subsequent weathering liberates preexisting cemented grains, thereby controlling texture.

Surface Expression

Surface expression of landslide material is hummocky, often superimposed on a rising slope. Hummocks are produced by the land-

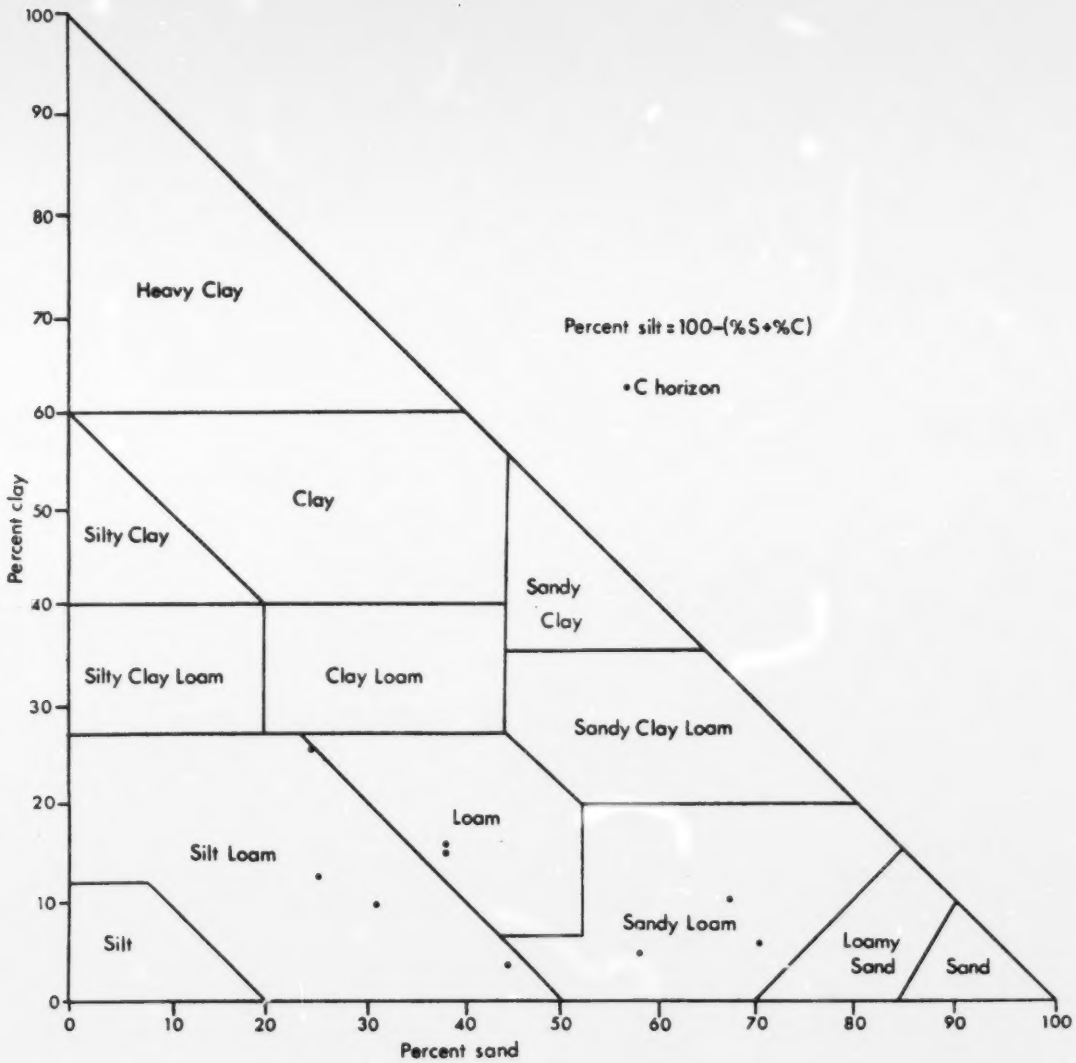

Figure 8 Textural variation among selected C horizons sampled on landslide material.

slide process, while the overall incline reflects bedrock control at some depth.

Thickness of landslide material is variable, controlled by individual factors for each slide such as volume of material, height of failure above the valley floor, steepness and channelling during the failure, type of terrain covered, and others. Most landslides are postglacial and immediately overlie a variety of unconsolidated materials, especially till on valley walls and lower slopes.

Discussion

Landslide material is separated from other colluvial material on the basis of its cataclysmic genesis. Other colluvium occurs on linear steeply inclined slopes and on average has smaller coarse fragments and a higher fine earth content.

Residuum on failed slopes is similar to landslide material but is not fragmental. Less violence is inferred in genesis of the former, as some structures remain intact despite an increase in the degree of jointing and displacement of beds.

Landslide material forms the principal landforms of the Garrone (GA) Ecosection in the Montane, Ishbel (IB) in the Lower Subalpine, and Boulder Pass (BP) in the Upper Subalpine, as well as the Miscellaneous Landscape Colluvial Landslide (CL). In the Alpine, a few tracts of Bow Summit 1 (BS1) are mapped on landslide material.

Many conditions can precipitate landslides,

but one of the most common is dip-slope failure due to undercutting or removal of lateral support (Cruden 1976). Plate 2 illustrates a valley wall in Jasper near Nigel Pass where this type of landslide has occurred and has the potential for further failure. A less common type of landslide from Dolomite Creek in Banff is shown in Plate 3. A rock glacier is interpreted to have spilled en masse over a cliff above the landslide. Melting of frozen blocks of unconsolidated material left the conical debris piles.

COLLUVIAL GENETIC MATERIAL

Colluvium is defined as any loose, heterogeneous, and incoherent mass of soil material and rock fragments deposited chiefly by gravity (Gary et al. 1972). Movement includes slow displacement such as soil creep and rapid events such as landslides, avalanches and rockfalls (C.S.S.C. 1978b). For purposes of the Banff-Jasper Ecological Land Classification, landslide and colluvial genetic materials were separated, the latter refering specifically to deposits generated by slow displacement and/or rapid motion of isolated fragments.

Colluvial genetic material is postglacial and modifies chiefly steep, glaciated valley walls. Surface form is usually linear and expressed as blankets, veneers and aprons, and is controlled by deposition and underlying bedrock. Colluvial material is generally shallowest (veneers) at the top of slopes and deepens downslope (blankets). Aprons occur along slope bases at major slope breaks and below steep rock walls. Irregular surface form occurs when the continuity of colluvial slopes is broken by one or more bedrock escarpments. Bedrock escarpments are common on some colluvial slopes. Colluvial veneers dominate on some slopes where colluvial deposits are thin over bedrock. Slopes on colluvial landforms are commonly 55 to 70% and range from 45 to 100%.

Soil creep (slow down slope colluviation of soil and rock) has been instrumental in forming many of the colluvial deposits in Banff and Jasper. Presently, active soil creep affects surface layers, thereby influencing soil development. Its effects on surface form and genetic material are negligible.

Snow avalanching is characteristic on some colluvial slopes. Varying amounts of material are deposited downslope during avalanche events. However, avalanche related fluvial activity is important to material accumulation on aprons below channelled tracks and couloirs. Fluvial material including mudflow deposits thinly mantle and interbed with colluvial material.

Other processes affecting colluvial landforms include slope failure, surface (sheet) erosion, solifluction and cryoturbation. Slope failure occurs on a few colluvial landforms and primarily encompasses slow mass movement (often rotational) of unconsolidated material plus partial failure of underlying bedrock downslope along a slip surface. Surface sheet erosion occurs locally and affects the upper sola of soils. Solifluction and cryoturbation occur infrequently, usually at high elevations.

The Miscellaneous Landscapes Talus (T) and Colluvial Rubble (CR) are also colluvial material.

The textural and chemical characteristics of colluvial material reflect source bedrock lithology. Continua of textural (coarse to fine) and chemical (from noncalcareous and alkaline) properties exist in the colluvial deposits of Banff and Jasper. For the purposes of this Ecological Land Classification the continua are categorized into three colluvial genetic material classes. Separation is based on textural and calcareousness properties reflected by three major categories of bedrock lithology (Table 5). The three colluvial genetic materials are: noncalcareous, coarse textured colluvium (Colluvium A) derived from medium to coarse grained, noncalcareous clastic strata; noncalcareous, medium textured colluvium (Colluvium B) derived from medium to fine grained, noncalcareous clastic strata; and calcareous, medium textured coiluvium (Colluvium C) derived from medium to fine grained, carbonate and calcareous clastic strata (Table 5).

COLLUVIUM A

Concept and Distribution

Modally, Colluvium A is noncalcareous (acidic), coarse textured colluvium derived from medium to coarse grained, noncalcareous clastic bedrock, mainly quartzite. Its major source is the Lower Cambrian Gog Group that dominates portions of the Main Ranges. Occasional occurrences are correlated to the Ordovician Mount Wilson Formation (e.g. near Pipestone Pass warden cabin in Banff) and quartz sandstone layers of the Permian-Pennsylvanian Rocky Mountain Group (e.g. north of Cascade Mountain in Banff). Colluvium A is the least extensive of the three colluvial genetic materials. Ecosites with Colluvium A as the principal genetic material are restricted to the Subalpine and Alpine Ecoregions. In the Lower Subalpine, colluvial landforms occasionally are admixtures of Colluvium A and Colluvium B. Some Main Range slopes at low elevations, where Gog Group quartzites are underlain by Precambrian Miette Group slates and shales, have colluvium composed of debris falling from both groups.

Surface Expression and Modifying Processes

Colluvial slopes consisting of Colluvium A

commonly occur as blankets and veneers overlying inclined bedrock on steep valley walls and as aprons along slope bases at major slope breaks and below steep rock walls. Exposed bedrock forms the subdominant portion of some colluvial slopes. Surface form is controlled by the amount of deposition and by the underlying bedrock. Colluvium A landforms have dominantly linear, inclined slopes commonly ranging from 45 to 100%. Colluvium A slopes with complex topography have linear slopes whose continuity is broken by one or more exceptionally steep bedrock escarpments.

Soil creep is a common surface modification affecting landforms comprised of Colluvium A. Soil creep indicates active colluviation affecting surface layers but its effects on surface form and genetic material characteristics are negligible. Effects on soil development, however, are significant.

Snow avalanching is characteristic of some colluvial slopes. Varying amounts of material are deposited down slope during avalanche events, therefore its effects on parent material and associated soils are variable. Its effects on surface form are virtually negligible but its effects on vegetation are great. Avalanche related fluvial activity is important to material accumulation on aprons below channelled tracks and couloirs. Fluvial material thinly mantles and interbeds with colluvial material.

Other processes affecting Colluvium A include slope failure, surface sheet erosion, solifluction and cryoturbation. Slope failure encompasses slow mass movement, often rotational, of unconsolidated material plus partial failure of underlying bedrock downslope along a slip surface. Such failed slopes are postglacial and, in some instances may still be active. Surface sheet erosion occurs locally and affects the upper sola of soils. Solifuction and cryoturbation occur infrequently, the latter only in the Upper Subalpine and Alpine.

Textural Properties

Colluvium A is coarse, referring to both texture and volume of coarse fragments. The fine earths are generally comprised of 60 to 85% sand and 0 to 10% clay. This range falls within the sandy loam and loamy sand textural classes defined by C.S.S.C. (1978a). Textural variation among selected Bm, BC and C horizon samples of Colluvium A is portrayed in Fig. 9. Angular coarse fragments, dominantly quartzite, commonly constitute 50 to 90% and occasionally 100% by volume of Colluvium A. Shaly and slaty fragments mix with quartzites on some colluvial slopes where Gog Group strata are underlain by Miette Group strata. Carbonate fragments are rare or absent.

Colluvium A and C are differentiated by textural and chemical properties; Colluvium A and B primarily by textural properties. Where it is necessary to differentiate phases of Colluvium A and B that have similar textures (e.g. in the 50 - 70% sand range), accessory features, including coarse fragments, soil development, and location are used. Colluvium A has the highest content of coarse fragments, most of which are quartzitic. Shale, slate or carbonate fragments are rare or absent. Stones and boulders are especially abundant in Colluvium A, its surfaces often being very stony.

Soils developed in Colluvium A are distinctive. They usually have deeply weathered sola, and thick, well developed eluvial (Ae) horizons, which are indicative of rapidly pervious, noncalcareous, coarse textured genetic material. Soils developed in Collvuium B and C genetic materials have thin sola with thin to absent Ae horizons.

Finally, Colluvium A, B and C are differentiated by the nature of the lithology of the bedrock outcrop from which the Colluvium was derived. Colluvium A is situated below cliffs or outcrops comprised of quartzites.

Calcareousness and Reaction Properties

Colluvium A is usually noncalcareous and acid, with pH values commonly ranging from 4.3 to 6.0. A low lime phase (<15% $CaCO_3$ equivalent) with higher pH (6.0 to 7.0) occurs locally but is characterized by deeply weathered, acidic soils. The low lime phase occurs when minor amounts of calcareous beds occur in the strata from which the colluvium is derived.

Colluvium A and B have similar low lime and low pH properties; whereas Colluvium C is usually chemically different but can have similar low lime phases. These are distinguished by textural and related properties and by associated soil development. Colluvium A is distinguished from Colluvium C because it is dominated by deeply weathered soils with extremely to strongly acidic (pH 5.5 or less) sola including, specifically, the B and underlying horizons to a thickness of 25 cm. Soils developed in the low lime phase of Colluvium C have medium acid to neutral (pH >5.5) lower sola.

Discussion

Colluvium A is noncalcareous and coarse textured, being derived primarily from quartzitic bedrock. It is least extensive of the three colluvial parent materials differentiated in Banff and Jasper. The Endless Chain (EN) and Tekarra (TK) Ecosections occur on colluvial slopes consisting of Colluvium A. The Fairview (FV) Ecosection occurs on colluvial slopes consisting of Colluvium A and/or Colluvium B.

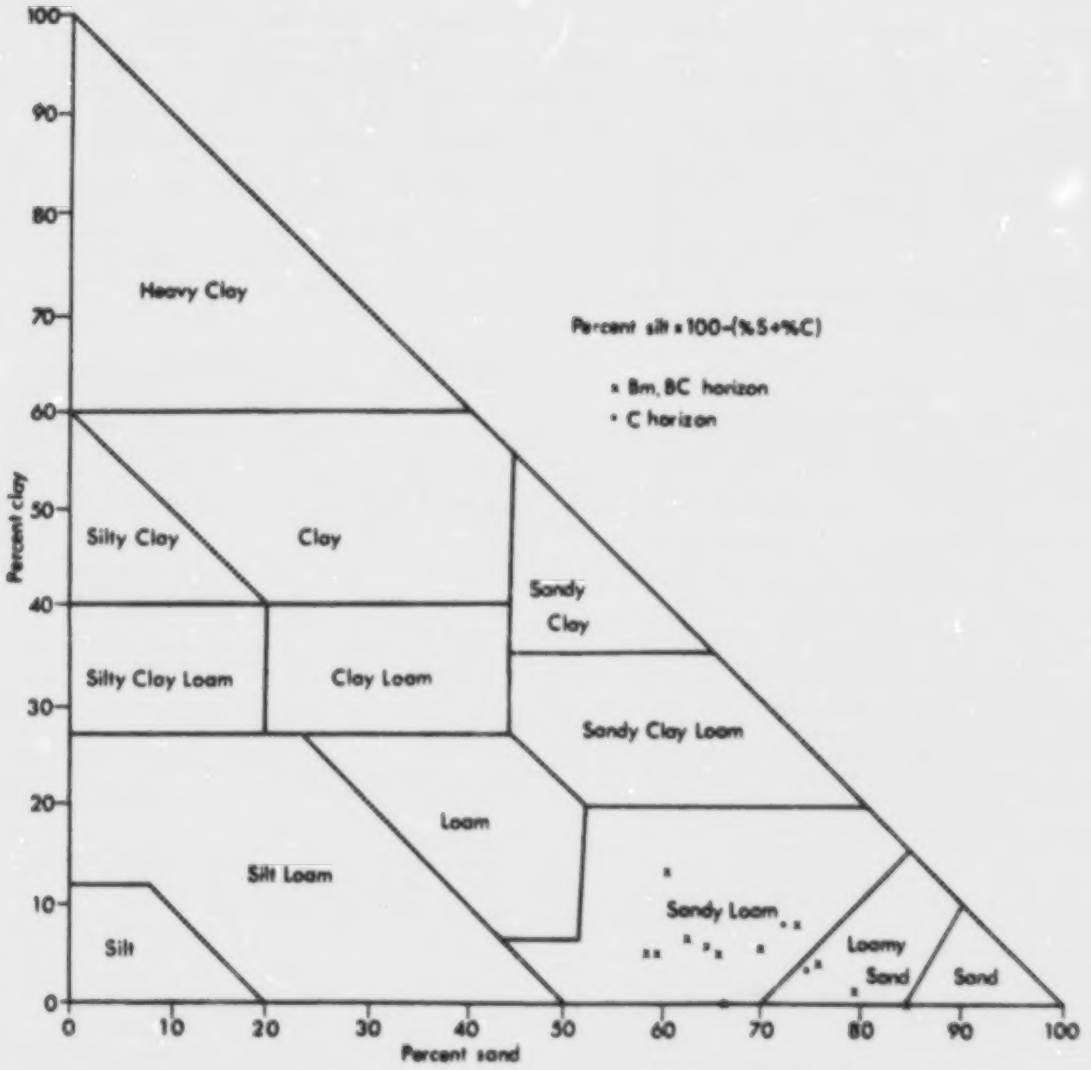

Figure 9 Textural variation among selected Bm, BC, and C horizon samples of noncalcareous, coarse textured colluvium (Colluvium A).

Miscellaneous Landscapes Talus (T) and Colluvial Rubble (CR) consist of Colluvium A in areas dominated by Gog Group strata.

COLLUVIUM B

Concept and Distribution

Modally, Colluvium B is noncalcareous (acidic), medium textured, colluvium derived from medium to fine grained, noncalcareous, clastic bedrock, mainly shale and slate. Its major source is the Precambrian Miette Group (slate and shale) that dominates portions of the Main Ranges geologic subprovince. Colluvium B also occurs in the Front Ranges but not as extensively. Colluvial materials in these eastern areas are derived from the noncalcareous, often carbonaceous, Mesozoic strata, namely the Jurassic and Lower Cretaceous strata of the Kootenay, Nikanassin and Luscar Formations and the Fernie Group. Colluvium derived from the Mesozoic sources is darker colored (dark browns and grays to black) than colluvium derived from the older strata (yellowish browns and browns).

Colluvium B is more extensive than Colluvium A. Colluvium B source areas are characterized by a distinctive subdued mountain landscape formed entirely in the recessive Miette Group and noncalcareous Mesozoic strata. Source bedrock is relatively uniform and its chemical and textural characteristics are transmitted to the colluvium. Colluvium B occurrences are restricted to the Subalpine

and Alpine Ecoregions. However, in the Lower Subalpine, colluvial landforms are occasionally admixtures of Colluvium B and Colluvium A. This is because some slopes in the Main Ranges, where Precambrian Miette Group slates and shales are capped by Gog Group quartzites, have colluvium compromised of debris falling from both groups. Colluvium intermediate in composition between Colluvium B and Colluvium C occurs when it is comprised of admixtures of slaty and carbonate or calcareous clastic strata which occur occasionally in the Front Ranges subprovince where calcareous strata adjoin or overlie the noncalcareous Mesozoic or Miette Group strata because of faulting.

Surface Expression and Modifying Processes

Colluvial slopes consisting of Colluvium B commonly occur as blankets and veneers overlying inclined bedrock on steep valley walls and as aprons along slope bases at major slope breaks and below steep rock walls. Exposed bedrock forms the subdominant portion of some colluvial slopes. Surface form is controlled by depth of deposition and by the underlying bedrock. Colluvium B landforms commonly have long, linear, inclined slopes ranging from 45 to 100%. Colluvium B slopes with complex topography have linear slopes whose continuity is broken by one or more steep bedrock escarpments.

Soil creep is a common surface modification affecting landforms comprised of Colluvium B. Soil creep indicates active colluviation affecting surface layers but its effects on surface form and genetic material characteristics are negligible. Effects on soil development, however, are significant.

Snow avalanching is characteristic of some colluvial slopes. Varying amounts of material are deposited downslope during avalanche events, therefore its effects on genetic material and associated soils are variable. Its effects on surface form are virtually negligible, however, its effects on vegetation are great. Avalanche related fluvial activity is important to material accumulation on aprons below channelled tracks and couloirs. Here fluvial material thinly mantles or becomes interbedded with colluvial material.

Other processes affecting Colluvium B include slope failure, surface sheet erosion, solifluction and cryoturbation. Slope failure encompasses slow mass movement, often rotational, of unconsolidated material plus partial failure of underlying bedrock downslope along a slip surface. Such failed slopes are postglacial and, in some instances may still be active. Surface sheet erosion occurs locally and affects the upper sola of soils. Solifluction and cryoturbation occur infrequently,the latter only in the Upper Subalpine and Alpine.

Textural Properties

Colluvium B is medium textured. The fine earths are generally comprised of 20 to 60% sand and 5 to 20% clay. This range falls within the silt loam, loam and sandy loam textural classes defined by C.S.S.C. (1978a). Textural variation among selected Bm, BC and C horizon samples is portrayed in Fig. 10. Increasing sand content accompanied by decreasing clay content corresponds to increased input of quartzite and sandstone from source areas above. Angular and thin, flat coarse fragments, dominantly slates and shales, commonly constitute 35% to 90%, and occasionally 100% by volume, of Colluvium B. Coarse fragment content usually increases with depth. Quartzites occasionally mix with Miette Group slates and shales when capped by Gog Group strata. Carbonate fragments also occur occasionally.

Colluvium B and C have similar textures and are differentiated by chemical properties. Colluvium B and A have similar chemical properties but are distinguished by textural differences. Accessory features, including coarse fragments, soil development, and location, are necessary to differentiate phases of Colluvium B and A with similar textures (e.g. 50 - 70% sand range) Colluvium B usually has a high content of coarse fragments consisting primarily of slates or shales rather than quartzites as in Colluvium A. In particular, Colluvium B is not as stony as Colluvium A.

Soils developed in Colluvium B have thin sola and thin, weakly developed or absent eluvial Ae horizons whereas soils developed in Colluvium A have thick sola and thick, well developed Ae horizons.

Finally, Colluvium A, B and C are differentiated by the nature of the lithology of the bedrock outcrop from which the colluvium was derived. Colluvium B is situated on or below slopes comprised of noncalcareous slates and shales.

Calcareousness and Reaction Properties

Colluvium B is usually noncalcareous and acid, ranging from extremely acid to medium acid (C.S.S.C. 1978a) with pH values commonly ranging from 4.3 to 6.0. A low lime phase (<5% $CaCO_3$ equivalent) with higher pH (6.0 to 7.0) occurs locally but is characterized by soils with acidic (pH 5.5 or less) sola. This phase is attributed to a minor influence of calcareous beds in the strata from which the colluvium is derived.

Colluvium B and A have similar low lime and low pH properties whereas Colluvium C is usually chemically different, but can have similar low lime phases differentiated by associated soil development. Colluvium B, includ-

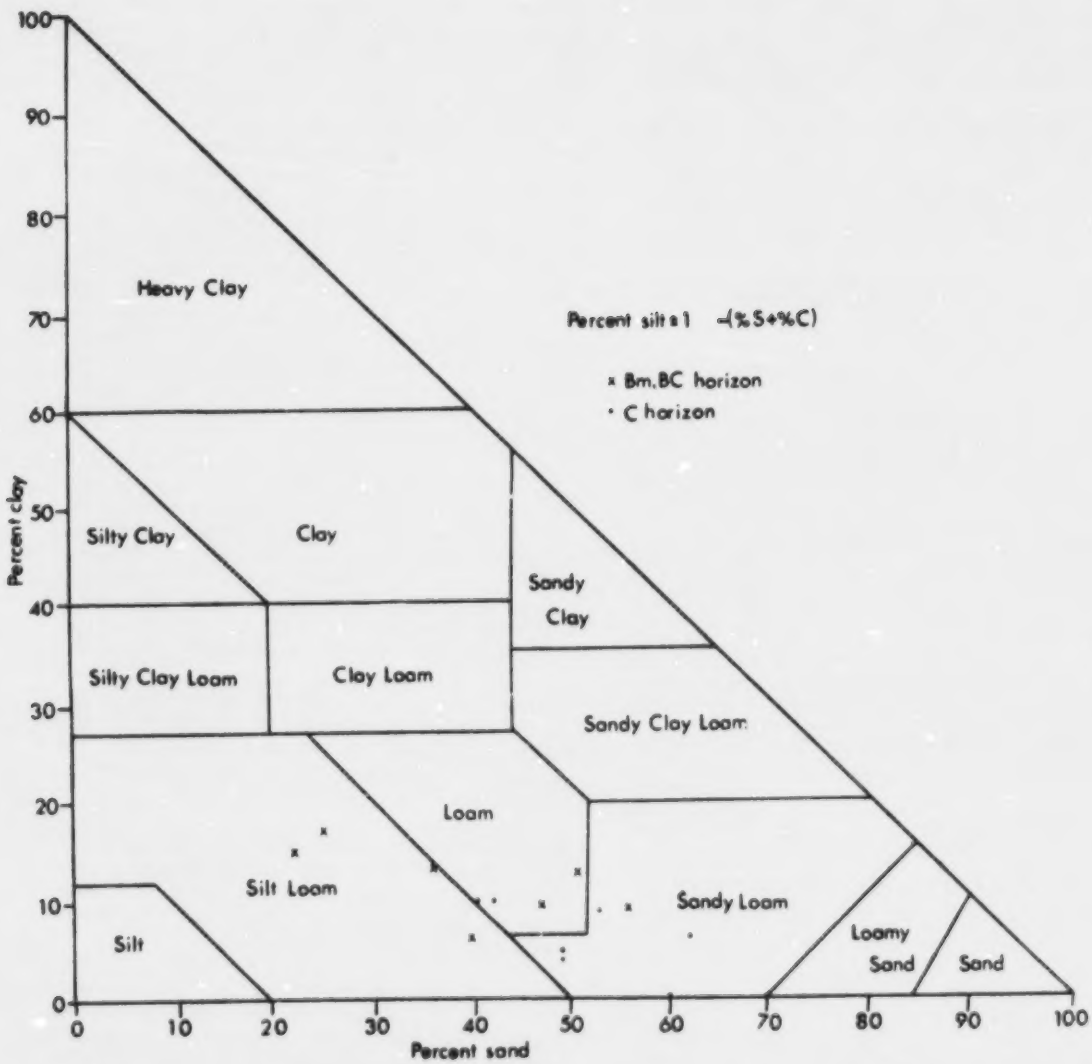

Figure 10 Textural variation among selected Bm, BC, and C horizon samples of noncalcareous, medium textured colluvium (Colluvium B).

ing its low lime phase, is dominated by soils with extremely to strongly acidic (pH 5.5 or less) sola including specifically, the B and underlying horizons to a thickness of 25 cm. Soils developed in the low lime phase of Colluvium C generally have medium acid to neutral (pH >5.5) lower sola.

Discussion

Colluvium B is noncalcareous and medium textured, being derived primarily from slaty and shaly bedrock. The Redoubt (RD) and Whitehorn (WH) Ecosections occur on colluvial slopes comprised of Colluvium B. The Fairview (FV) Ecosection occurs on colluvial slopes comprised of Colluvium B and/or Colluvium A.

Miscellaneous Landscapes Talus (T) and Colluvial Rubble (CR) consist of Colluvium B in areas dominated by Miette Group and noncalcareous Mesozoic strata, mainly slates and shales.

COLLUVIUM C

Concept and Distribution

Modally, Colluvium C is calcareous (neutral to alkaline), medium textured, colluvium derived from carbonate and calcareous clastic strata. These strata are common in both the Main and Front Ranges (Fig. 4).

Colluvium C is the most extensive of the three colluvial genetic materials because the

carbonate and calcareous clastic strata are most extensive, often overlying or interbedded with noncalcareous strata. Calcareous strata are abundant in all three Ecoregions of Banff and Jasper.

Surface Expression and Modifying Processes

Colluvial landforms consisting of Colluvium C commonly occur as blankets and veneers overlying inclined bedrock on steep valley walls and as aprons along slope bases at major slope breaks and below steep rock walls. Exposed bedrock forms the subdominant portion of some colluvial slopes. Surface form is controlled by thickness of deposition and by the underlying bedrock. Colluvium C landforms commonly have long, linear, inclined slopes ranging from 45 to 100%. Those landforms with complex topography have linear slopes whose continuity is broken by one or more exceptionally steep bedrock escarpments.

Soil creep is a common surface modification affecting landforms comprised of Colluvium C. Soil creep indicates active colluviation affecting surface layers but its effects on surface form and genetic material characteristics are negligible. Effects on soil development, however, are significant.

Snow avalanching is characteristic of some colluvial slopes. Varying amounts of material are deposited downslope during avalanche events therefore its effects on genetic material and associated soils are variable. Its effects on surface form are virtually negligible but its effects on vegetation are great. Avalanche related fluvial activity is important to material accumulation on aprons below channelled tracks and couloirs. Fluvial material thinly mantles or is interbedded with colluvial material.

Other processes affecting Colluvium C include slope failure, surface sheet erosion, solifluction and cryoturbation. Slope failure encompasses slow mass movement, often rotational, of unconsolidated material plus partial failure of underlying bedrock downslope along by a slip surface. Such failed slopes are postglacial and, in some cases may still be active. Surface sheet erosion occurs locally and affects the upper sola of soils. Solifluction and cryoturbation occur infrequently, the latter only in the Upper Subalpine and Alpine.

Textural Properties

Colluvium C is medium textured. The fine earths are generally comprised of 20 to 60% sand and 0 to 25% clay. This range falls within the silt loam, loam and sandy loam textural classes defined by C.S.S.C. (1978a). Textural variation among selected BC and C horizon samples of Colluvium C is portrayed in Fig. 11. Increasing sand content and decreasing clay content corresponds to increased input of quartzite and sandstone material from source areas above. Angular coarse fragments commonly constitute 35 to 90% and occasionally 100% by volume of Colluvium C. Coarse fragment content usually increases with depth. A high proportion are carbonate and calcareous clastic fragments.

Calcareousness and Reaction Properties

Colluvium C is strongly to extremely calcareous and neutral to mildly alkaline in reaction. Calcium carbonate equivalent content commonly ranges from 30 to 95%; pH values from 7.0 to 7.8. A low lime phase with carbonate content ranging from 1 to 15% is important in some areas where noncalcareous clastic strata are extensive. The most extensive areas of low lime colluvium occurs in the Front Ranges of eastern Banff and Jasper.

The low lime phase of Colluvium C is distinguishable from the low lime phases of Colluvium A and B by its reaction and by the soils that develop on it. The reaction (pH 6.8 to 7.8) of the low lime phase of Colluvium C remains comparable to that of modal Colluvium C. Colluvium C, including its low lime phase, is dominated by soils with medium acid to neutral (pH >5.5) lower sola including specifically, the B and underlying horizons to a thickness of 25 cm. This is in contrast to soils developed in the low lime phases of Colluvium A and B which have extremely to strongly acidic (pH 5.5 or less) sola. Overall, Colluvium C soils are characterized by thin sola and weakly to moderately developed B horizons rather than having thicker sola and Ae horizons as in Colluvium A and B. Occasionally, Colluvium C has advanced soils with strongly developed B horizons occurring in a thin, altered, medium textured, eolian material (Eolian material B) veneer.

Discussion

Colluvium C is calcareous and medium textured, being derived primarily from carbonate and calcareous clastic strata. It is the most extensive of the three colluvial genetic materials differentiated in Banff and Jasper. The Bow Summit (BS), Sawback (SB) and Wildflower (WF) Ecosections occur on colluvial landforms consisting of Colluvium C. Low lime phases of Colluvium C occur in the Sawback 5 (SB5) and Wildflower 7 (WF7) Ecosites.

A dark colored phase of Colluvium C is common in eastern regions of both parks. Its color (dark browns and grays to black) is attributed to incorporation of material from carbonaceous Mesozoic strata. The normal color of Colluvium C is much lighter and ranges through the browns and yellowish browns to gray browns and grays.

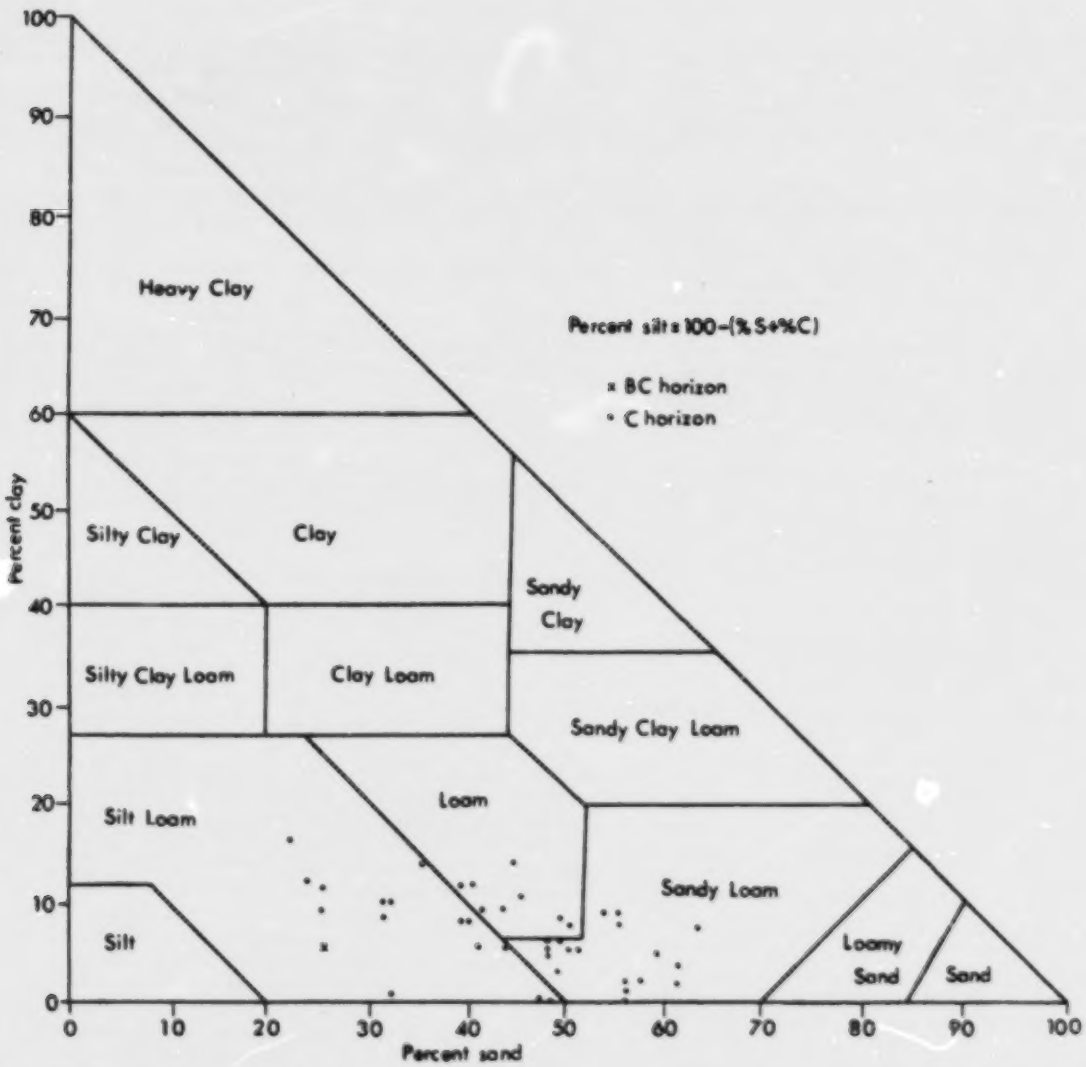

Figure 11 Textural variation among selected BC, and C horizon samples of calcareous, medium textured colluvium (Colluvium C).

Miscellaneous Landscapes Talus (T) and Colluvial Rubble (CR) consist of Colluvium C in areas dominated by carbonate and calcareous clastic strata.

MORAINAL GENETIC MATERIAL

Morainal material (till) is defined as unsorted and unstratified drift deposited by and underneath a glacier without subsequent reworking by glacial meltwater (Gary et al. 1972). Glaciation was a major factor in shaping the landscape of Banff and Jasper National Parks; hence, morainal deposits occur extensively. Till is occasionally intimately associated with ice contact stratified drift. Both are collectively considered glacial deposits as opposed to the proglacial materials, such as glaciofluvial and glaciolacustrine.

Morainal topography frequently dominates valley walls, broad valley floor benchlands, cirque basins, cols, and shoulders, even though veneers of other genetic materials often thinly mantle the till. Till thickness is variable, generally increasing downslope, with the thickest deposits occurring at the lowest elevations, except on benchlands where depths are highly variable. Surface form most often reflects bedrock control; hence, morainal blankets and veneers overlying inclined, hummocky, and ridged bedrock are abundant. On broad benchlands, surface form also directly reflects deposition and includes both hummocky and ridged moraine. Slope failure is a postglacial

process that often produces hummocky surfaces. Morainal landform slopes commonly range from 5 to 70%.

Three, and possibly up to five, major Pleistocene glacial advances and readvances occurred in the main valleys of the Canadian Rocky Mountains (Stalker 1963, 1969, McPherson 1970, Harris and Boydell 1972, Rutter 1972, Shaw 1972, Fox 1974, Roed 1975). There is some evidence to suggest the last deglaciation of major valleys in Banff and Jasper occurred 9000 to 9500 years B.P. (Westgate and Dreimanis 1967, Rutter 1972, Roed 1975). Recent moraines occur near the numerous glaciers and icefields presently existing in the Main Ranges geologic subprovince, particularly near the Continental Divide. These were deposited during and after the Neoglacial maximum, thought to be early to mid-nineteenth century (Heusser 1956, Gardner 1972, Kucera 1972).

Textural and chemical characteristics of morainal material do not reflect glacial chronology. Source bedrock lithology is more important (Rutter 1972, Stalker 1973). Lithologic properties were imparted by the various strata and were admixed by glaciation. However, mixing was not so complete as to have created homogeneous morainal material. Therefore, continua of textural (from coarse to fine) and chemical (from noncalcareous and acidic to highly calcareous and alkaline) properties exist in the tills of Banff and Jasper. The continua are broken and organized to identify, for the purposes of this Ecological Land Classification, three till genetic material units (Table 6). Separation is based on textural and calcareousness properties that can be traced to three major groups of bedrock lithology. The three till parent materials are: (1) noncalcareous, coarse textured till (Till A) derived from medium to coarse grained, noncalcareous, clastic strata; (2) noncalcareous, medium textured till (Till B) derived from medium to fine grained, noncalcareous clastic strata; and (3) calcareous, medium textured till (Till C) derived from medium to fine grained, carbonate and calcareous clastic strata.

TILL A

Concept and Distribution

Modally, Till A is noncalcareous (acidic), coarse textured, glacial till derived from medium to coarse grained, noncalcareous clastic bedrock, mainly quartzite. Its major source is the Lower Cambrian Gog Group (quartzite) that dominates portions of the Main Ranges geologic subprovince (Fig. 4). Local occurrences are correlated to the Mount Wilson Formation (e.g. near Pipestone Pass warden cabin in Banff) and quartz sandstone layers of the Permian-Pennsylvanian Rocky Mountain Group (north of Cascade Mtn. in Banff).

Till A is the least extensive of the three till genetic material units. The structural style of the Main Ranges—Gog Group quartzites underlain by Precambrian Miette Group slates and shales and capped by younger carbonate strata—favors admixtures of till derived from contrasting bedrock sources. Hence, Till A does not often extend great distances beyond quartzitic source areas, unless morainal material from other sources has not been introduced from tributary valleys and valley walls. For these reasons, Till A occurrences are restricted to the Subalpine and Alpine Ecoregions. It is not known to occur in the Montane.

Surface Expression and Modifying Processes

Moraines consisting of Till A commonly occur as blankets overlying inclined bedrock on valley walls, blankets and veneers overlying ridged and hummocky bedrock on higher elevation shoulders, cirque basins, and cols. Its existence on low elevation benchlands in major valleys is very limited. Thick moraines with hummocky surfaces, produced directly by deposition (e.g. old rock glaciers) and occasionally by post glacial slope failure, occur sporadically. Ridged moraine, reflecting deposition rather than underlying bedrock surfaces, includes local features such as lateral and terminal moraines. Slopes on Till A moraines commonly range from 5 to 70%.

Slope failure, gullying, and avalanching are common surface modifications affecting moraines comprised of Till A. Slope failure is of two types, the most common encompassing old (inactive) rock glaciers that originated as talus and protalus ramparts below rock walls. In some cases, these have introduced Till A, derived from hanging cirques and rock walls, to downslope positions dominated by other till parent materials. The second, less common type of slope failure encompasses slow mass movement, often rotational, of till or till plus underlying bedrock downslope, guided by a slip surface. Such failed slopes are postglacial and, in some instances, may still be active.

Gullies are steep-sided narrow, subparallel ravines produced by fluvial erosion, mainly intermittent streams created by concentration of surface runoff from feral slopes above. Gullied moraine is most common on linear valley walls below hanging cirques and steep rock and colluvial (feral) slopes that act as the source (fetch) areas for the incising streams. Some ridged and hummocky terrain in cirques and cols is dissected by a few, nonparallel gullies associated with intermittent and permanent streams. Process status may be active or inactive.

Although snow avalanching is common, its effects on moraine surface form, parent material, and associated soils are virtually negligible. Effects on vegetation, however, are great. Other modifying processes have limited impact. Surface sheet erosion occurs locally and affects upper sola of soils. Occasional patches of lag stones and boulders are manifestations of historic surface erosion. Shallow surface colluviation also occurs locally on steep moraines and affects soil sola. These two processes are particularly abundant on avalanched localities and burned areas. Solifluction and cryoturbation occur infrequently in the Upper Subalpine and Alpine.

Textural Properties

Till A is coarse textured, referring to both the fine earth fraction and volume of coarse fragments. The fine earths are generally comprised of 60 to 85% sand and 0 to 10% clay. This range falls within the sandy loam and loamy sand textural classes defined by C.S.S.C. (1978a). Textural variation among selected BC and C horizon samples of Till A is portrayed in Fig. 12. Increasing clay content accompanied by decreasing sand content corresponds to increased input of finer grained material from source areas. In many instances, Till A tends to become slightly finer textured with increasing depth. Rounded and subrounded coarse fragments, dominantly quartzite, commonly constitute 35 to 70% by volume of Till A.

Tills A and C are differentiated by textural and chemical properties; Tills A and B pri-

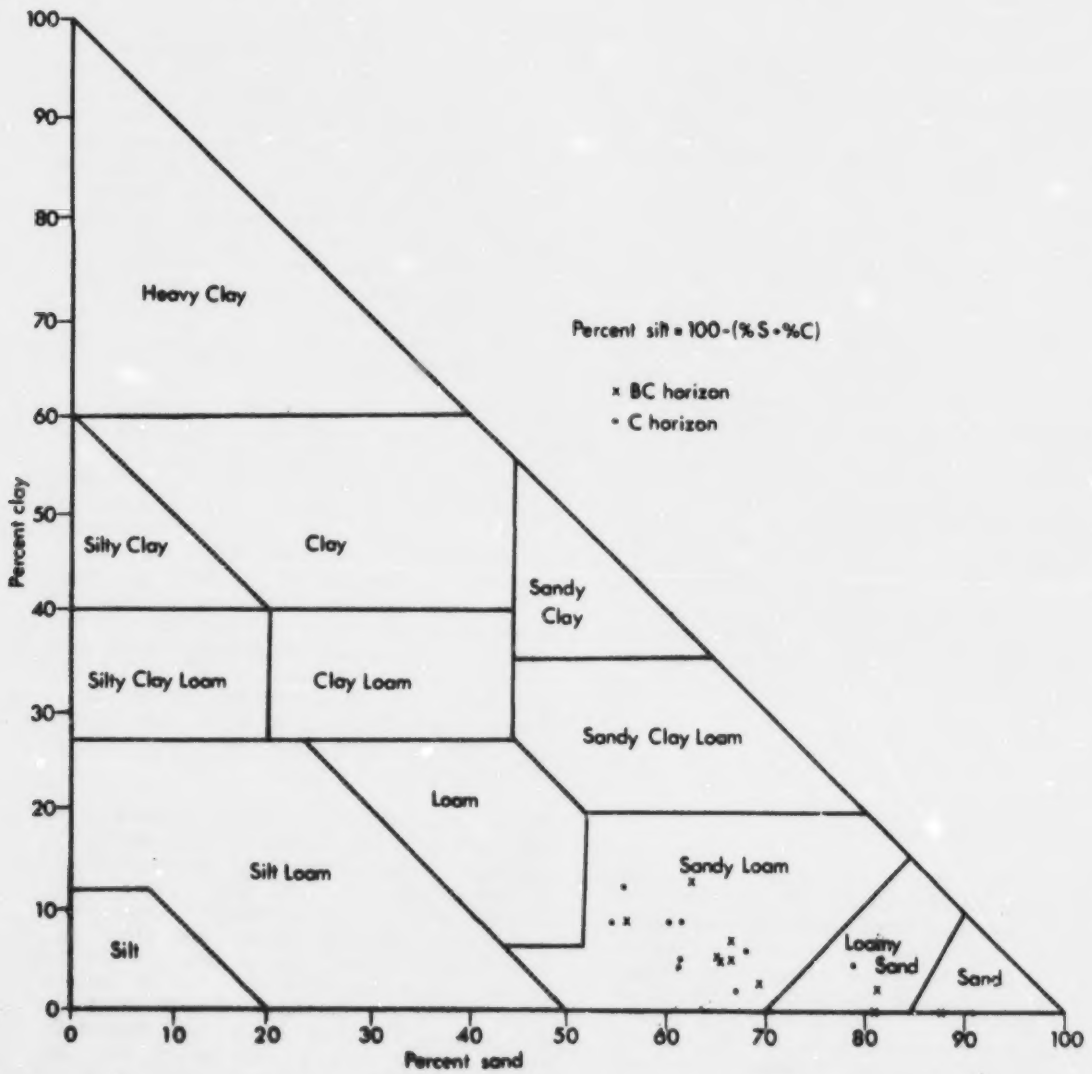

Figure 12 Textural variation of selected BC and C horizon samples of coarse textured, noncalcareous till (Till A).

marily by textural properties. Accessory characteristics, including coarse fragments, thickness and degree of soil development and location, are necessary to differentiate phases of Tills A and B that have similar textures (e.g. in the 50-70% sand range). Till A has the highest content of coarse fragments, most of which are quartzitic. Shale, slate, or carbonate fragments are rare or absent. Stones and boulders are especially abundant in Till A, its morainal surfaces often being quite stony.

Soils developed on Till A are distinctive. They usually have deeply developed sola and thick, well developed eluvial (Ae) horizons, features indicative of the rapidly pervious, noncalcareous, coarse textured genetic material. Their BC or lower B horizons are often weakly cemented (duric tendencies). Soils developed in Till B and C genetic materials have thin sola with thin to absent Ae horizons. Where the Ae horizons are developed in veneers of altered, medium textured eolian material (Eolian material B), Ae horizon thickness is not a useful criterion for separating Tills A, B, and C.

Finally, Tills A, B, and C are differentiated by the nature of the lithology of the bedrock from which the till was derived as inferred from the location of the respective moraines.

Calcareousness and Reaction Properties

Till A is usually noncalcareous and acidic, with pH values of about 4.3 to 6.0. A low lime phase (<15% $CaCO_3$ equivalent) with higher pH (6.0 to 7.0) occurs locally but is overlain by deeply weathered, acidic soils. The increased pH is attributed to added carbonates through groundwater discharge or the incorporation of small amounts of calcareous material in the derivation of the till.

The low lime phase of Till A is similar to the low lime phase of Till C. These low lime phases usually can be distinguished by textural properties and by associated soil development. Till A (including its low lime phase) can be distinguished by deeply developed soils with extremely to strongly acidic (pH 5.5 or less) sola including the B and underlying horizons to a thickness of 25 cm. Soils developed in the low lime phase of Till C generally have medium acid to neutral (pH >5.5) lower sola.

Discussion

Till A is noncalcareous and coarse textured, being derived primarily from quartzitic bedrock. It is least extensive of the three till genetic material units differentiated in Banff and Jasper. The Eiffel (EF), Moraine Lake (ML), and Larch Valley (LV) Ecosections occur on moraines consisting of Till A. It is a minor constituent of the Cavell 1 (CA1), Consolation Valley 1 (CV1), and Egypt 3 (EG3) Ecosites.

Till A and coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) are intimately associated in some areas, having shared depositional environments and source lithology. The most notable example of this association is in the Blue Creek area in Jasper.

TILL B

Concept and Distribution

Modally, Till B is noncalcareous (acidic), medium textured, glacial till derived from medium to fine grained, noncalcareous, clastic bedrock, mainly shale and slate. Its major source is the Precambrian Miette Group (slate and shale) that dominates portions of the Main Ranges geologic subprovince (Fig. 4). Till B also occurs, but less extensively, in the Front Ranges geologic subprovince. Source strata in these eastern areas are the noncalcareous, often carbonaceous, Jurassic and Lower Cretaceous strata of the Kootenay, Nikanassin, and Luscar Formations and the Fernie Group. Till derived from these Mesozoic sources is darker colored (dark browns and grays to black) than till derived from the older strata (yellowish browns and browns).

Till B is more extensive than Till A. Till B extends some distance beyond the several small, but distinctive, source areas characterized by subdued mountain landscape formed entirely in the recessive Miette Group and noncalcareous Mesozoic strata. Source bedrock in this situation is relatively uniform and its characteristics are transmitted to the till. However, introduction of material derived from other sources in tributary valleys and on valley walls tends to alter the till characteristics. Tills derived from admixtures of slaty and quartzitic sources occur most often in the Main Ranges subprovince where the Gog Group strata conformably overlie the Miette Group strata. Till B occurs infrequently at low elevations and is confined to chiefly the Subalpine and Alpine Ecoregions.

Surface Expression and Modifying Processes

Morainal landforms consisting of Till B commonly occur as blankets overlying inclined bedrock on valley walls, blankets and veneers overlying ridged and hummocky bedrock on benchlands, shoulders, cirque basins, and cols. Thick moraines with hummocky surfaces, produced directly by deposition (e.g. old rock glaciers) and occasionally by postglacial slope failure, occur sporadically. Ridged morainal landforms reflecting deposition include local features such as lateral and terminal moraines. Slopes on Till B moraines commonly range from 5 to 70%.

Slope failure, solifluction, and avalanching are common surface modifications sometimes affecting landforms comprised of Till B. Slope failure is of two types. The most common, encompassing old (inactive) rock glaciers, have sometimes introduced Till B, derived from shoulders and cols, to downslope positions dominated by other till units. An example occurs in the upper Red Earth Creek valley in Banff where hummocky moraine consisting of Till B derived from the Gibbon Pass area was superimposed on the linear north wall of the valley. Morainal blankets and veneers consisting of Till C mantle this same wall up and down-valley beyond the limits of the old rock glacier. The second type of slope failure is less common and encompasses slow mass movement, often rotational, of till or till plus underlying bedrock downslope along a slip surface. Such failed slopes are postglacial and, in some instances may still be active.

Solifluction, the slow mass flow downslope of saturated material (Washburn 1973), is most active at high elevations under moderately well to poorly drained conditions with episodic seepage. Movement is probably greatest in the spring when meltwater is abundant and soils are still partially frozen. Cryoturbation is an associated process occurring sporadically in the high elevation areas. Both are most abundant in eastern Banff and Jasper on till derived from Mesozoic strata. Neither significantly affect textural and chemical properties of the till, except for partial sorting. Landform surface expression, however, may be subtly altered by the occurrence of solifluction lobes, benches, and streams (Washburn 1973) on a small scale and solifluction sheets over expansive areas. Circles, nets and micro-hummocks are manifestations of cryoturbation. Both processes significantly affect soil development.

Although snow avalanching is common, its effects on moraine surface forms, parent material, and associated soils are virtually negligible. Effects on vegetation, however, are great.

Gullies, including the few isolated nonparallel ravines associated with well established, intermittent and permanent streams, occur infrequently on Till B moraines. On Till A or C moraines, gullies are abundant. This anomolous phenomenon is explained, in large part, by surrounding landscape features. Till B moraines often occupy high elevation subdued landscape, consequently, the fetch area for collecting surface runoff does not exist. Till B moraines on valley walls are often bounded above by well defined shoulders that intercept concentrated runoff from adjoining feral slopes.

Other modifying processes have limited impact. Surface sheet erosion occurs locally and affects upper sola of soils. Shallow surface colluviation also occurs locally on steep moraine and affects soil sola. These two processes are particularly abundant on avalanched localities and burned areas.

Textural Properties

Till B is medium textured in terms of both the fine earth fraction and volume of coarse fragments. The fine earths are generally comprised of 30 to 60% sand and 5 to 25% clay. This range falls within the silt loam, loam, and sandy loam textural classes defined by C.S.S.C. (1978a). Textural variation among selected BC and C horizon samples of Till B is portrayed in Fig. 13. Increasing sand content accompanied by decreasing clay content corresponds to an increased component of quartzite and sandstone material from source areas. Subrounded and thin, flat coarse fragments commonly constitute 20 to 50%, by volume, of Till B.

Tills B and A are distinguished by textural differences. When the texture is comprised of 50 to 70% sand, accessory features such as coarse fragments, soil development, and location, are necessary to differentiate moraines into Till A or Till B. Till B is not as stony as Till A and the coarse fragments are mainly slates or shales.

Soils developed on Till B have thin sola and thin, weakly developed or absent eluvial (Ae) horizons. Soils developed on Till A have thick sola and thick, well developed Ae horizons. Where the Ae horizons are developed in veneers of altered medium textured eolian material (Eolian material B), Ae horizon thickness is not a useful criterion for seperating Tills A, B, and C.

Finally, Tills A, B, and C are differentiated on the nature of the lithology of the bedrock from which each was derived, as inferred from the location of the respective moraines.

Calcareousness and Reaction Properties

Till B is usually noncalcareous and acid with pH values of about 4.3 to 6.0. A low lime phase (<5% $CaCO_3$ equivalent) with higher pH (6.0 to 7.0) occurs locally but has soils with acidic (pH 5.5 or less) sola. This phase is attributed to carbonate additions through groundwater discharge or the incorporation of some calcareous material in the derivation of the tills.

The low lime phase of Till B is similar to the low lime phase of Till C. The low lime phase of Till B is usually dominated by soils with extremely to strongly acidic (pH 5.5 or less) sola including the B and underlying horizons to a thickness of 25 cm. Soils developed in the low lime phase of Till C generally have

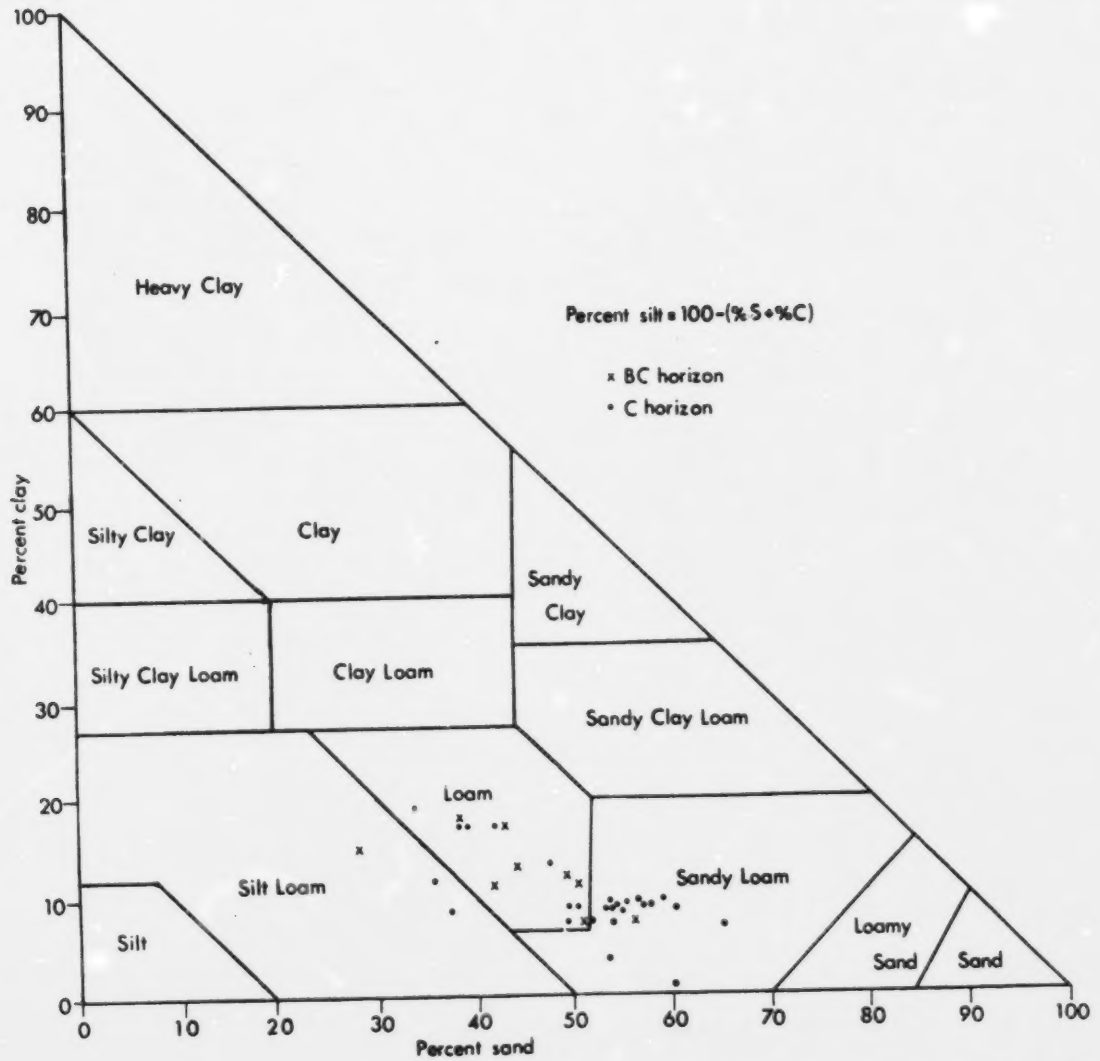

Figure 13 Textural variation of selected BC and C horizon samples of the medium textured, noncalcareous till (Till B).

medium acid to neutral (pH >5.5) lower sola.

Discussion

Till B is noncalcareous and medium textured, being derived primarily from slaty and shaly bedrock. The Cavell (CA), Egypt (EG), and Jonas (JN) Ecosections occur on moraines comprised of Till B. Moraines comprising the Sphinx 1 and 2 (SX1, SX2) Ecosites consist predominantly of Till B. Tills B and C are codominant in the moraines forming the Consolation Valley 1 (CV1) and Sphinx 3 (SX3) Ecosites. The dark colored phase of Till B, derived from the noncalcareous Mesozoic shales is subdominant in moraines forming the Tyrrell (TR) and Snowflake (SF) Ecosections. This same phase is a minor constituent of the Goat 2 (GT2) Ecosite.

Till B and the medium-stratified phase of Ice Contact Stratified Drift A, also derived from slates and shales, are intimately associated in a few areas such as the upper Miette River valley in Jasper and the Eisenhower Junction area in Banff.

TILL C

Concept and Distribution

Modally, Till C is calcareous (neutral to alkaline), medium textured glacial till derived from carbonate and calcareous clastic strata.

These strata are common in both the Main and Front Ranges subprovinces (Fig. 4).

Till C is the most extensive of the three till parent materials because the carbonate and calcareous clastic strata are most extensive, often capping or intercalating with noncalcareous strata. Additionally, only small amounts of calcareous rock material are necessary to produce Till C. It is abundant in all three Ecoregions.

Surface Expression and Modifying Processes

Moraines consisting of Till C commonly occur as blankets overlying inclined bedrock of valley walls, blankets and veneers overlying ridged and hummocky bedrock on benchlands, shoulders, cirque basins and cols. Thick moraines with hummocky surfaces, produced directly by deposition (e.g. old rock glaciers) and by postglacial slope failure, occur sporadically. Ridged moraine, reflecting deposition as opposed to control by underlying bedrock surfaces, includes local features such as lateral and terminal moraines and more expansive areas such as the fluted ground moraine in the Bow River valley near Baker Creek (Rutter 1972). Limited areas of inclined moraine occur along creek and river channels. These are short, linear, erosional slopes created by the down- and side-cutting action of present and historical streams through the glacial deposits of valley floor benchlands and valley walls. Slopes on Till C moraines commonly range from 5 to 70%. Slopes <5% occur locally on some benchlands and have an undulating surface expression.

Slope failure, gullying, solifluction, and avalanching are common surface modifications affecting moraines comprised of Till C. Slope failure is of two types. The first encompasses inactive rock glaciers that originated as talus and protalus ramparts below rock walls. In some cases, these have introduced Till C, derived from hanging cirques and rock walls, to downslope positions dominated by other till parent materials. The second type encompasses slow, often rotational, downslope mass movement of till or till plus underlying bedrock along a slip surface. Such failed slopes are postglacial and in some instances may still be active.

Gullies are steep-sided, narrow, subparallel ravines produced by fluvial erosion. This erosion is mainly by intermittent streams created by concentration of surface runoff from feral slopes above. Gullied morainal landforms are most common on linear valley walls below hanging cirques, and steep rock and colluvial (feral) slopes that act as the source (fetch) areas for the incising streams. Some ridged and hummocky terrain in cirques and cols is dissected by a few nonparallel gullies associated with intermittent and permanent streams. Process status may be active or inactive.

Solifluction, the slow mass flow downslope of saturated material (Washburn 1973), is most active at high elevations under moderately well to poorly drained conditions with episodic seepage. Movement is probably greatest in the spring when meltwater is abundant and soils are still partially frozen. Cryoturbation is an associated process occurring sporadically in high elevation areas. Both are most abundant in eastern Banff and Jasper on till derived from Mesozoic strata. Neither significantly affect textural and chemical properties of the till, except for partial sorting. Landform surface expression, however, may be subtly altered by the occurrence of solifluction lobes, benches, and streams (Washburn 1973) on a small scale although solifluction sheets can occur over expansive areas. Circles, nets, and microhummocks are manifestations of cryoturbation. Both processes significantly affect soil development.

Although snow avalanching is common, its effects on moraine surface form, genetic material, and associated soils are virtually negligible. Effects on vegetation, however, are great. Other modifying processes have limited impact. Surface sheet erosion and shallow surface colluviation are important on some of the steepest morainal slopes, especially if burned or avalanched. These two processes affect soil development.

Textural Properties

Till C is medium textured, in terms of both the fine earth fraction and volume of coarse fragments. The fine earths are generally comprised of 20 to 60% sand and 5 to 27% clay. This range falls within the silt loam, loam, and sandy loam textural classes defined by C.S.S.C. (1978a). Textural variation among selected C horizon samples of Till C is portrayed in Fig. 14. Increasing sand content, accompanied by decreasing clay content, corresponds to increased input of quartzite and sandstone material from source areas. A coarse textured phase (<70% sand), with a higher than normal content of medium and coarse grained clastics, occurs sporadically. A fine textured phase, higher than normal in silt and clay content, is of local importance in the Main Ranges subprovince. It is probably derived from argillaceous limestone strata. Rounded, subrounded, and thin, flat coarse fragments commonly constitute 20 to 50%, by volume, of Till C. A high proportion are carbonate and calcareous clastic fragments.

Calcareousness and Reaction Properties

Till C is calcareous and neutral to mildly alkaline in reaction. Calcium carbonate equivalent content commonly ranges from 15 to 85%, pH values from 7.0 to 7.8. Till C with pH >7.8 and lime content >85% is rare. However, a low lime phase, with car-

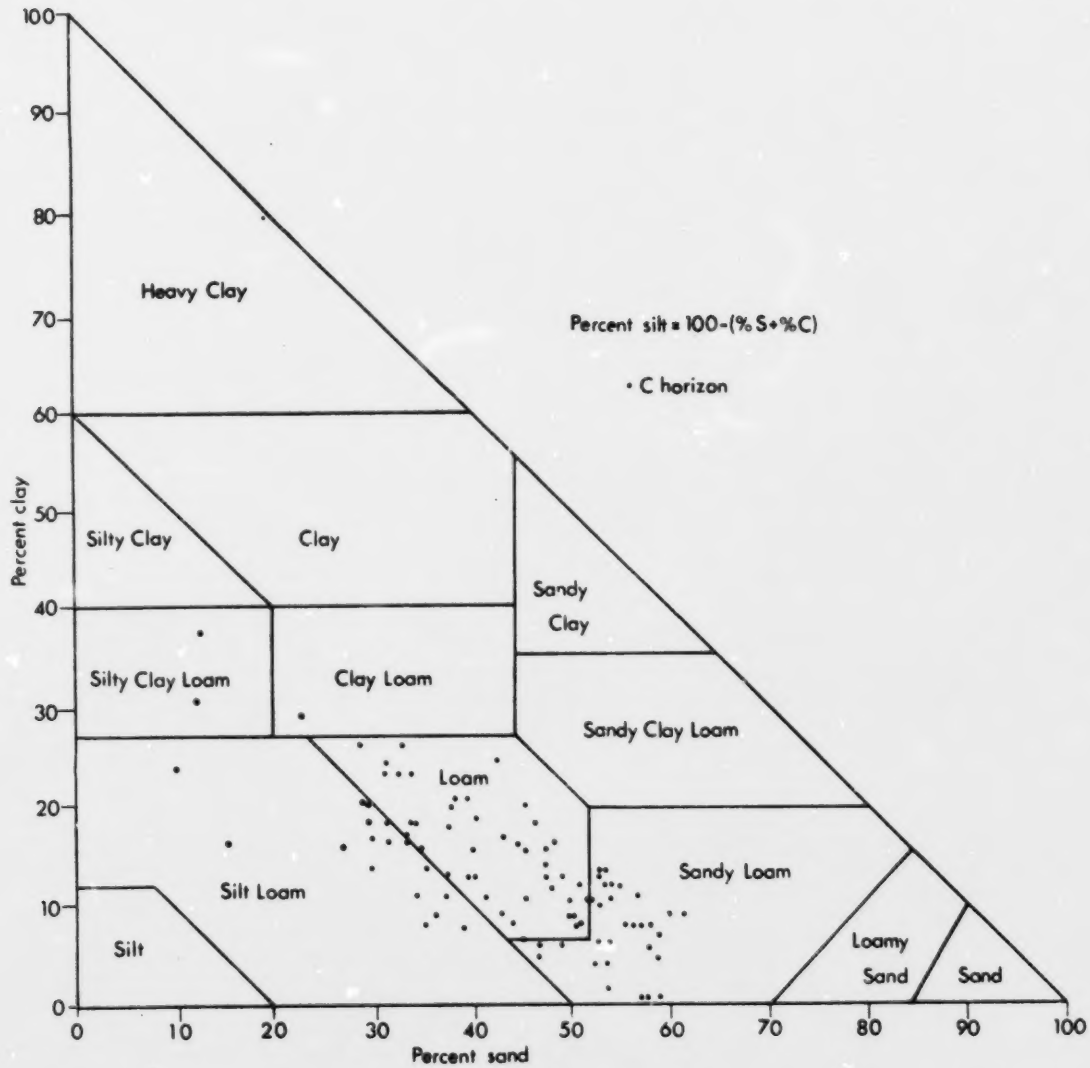

Figure 14 Textural variation of selected C horizon samples of calcareous, medium textured till (Till C).

bonate content ranging from 1 to 15%, is important in some areas where noncalcareous clastic strata are extensive. The most extensive example of low lime till occurs in the middle Athabasca and lower Miette River valleys upstream from Jasper townsite where it is underlain by the dominantly noncalcareous strata comprising the Miette Group. Additionally, it is dominant or codominant on morainal landforms forming the Panorama Ridge 3 (PR3) and Consolation Valley 1 (CV1) Ecosites.

Till C's low lime phase is distinguishable from the low lime phases of Tills A and B by its reaction and by the soils that develop on it. Even though containing low amounts of carbonate, the reaction of the low lime phase remains comparable (with pH values of 6.8 to 7.8) to that of normal Till C (neutral to mildly alkaline). Till C, including its low lime phase, is dominated by soils with medium acid to neutral (pH >5.5) lower sola including the B and underlying horizons to a thickness of 25 cm. Soils developed in the low lime phases of Tills A and B have extremely to strongly acidic sola (pH 5.5 or less). Overall, Till C soils are characterized by thin sola and a variety of B horizons, depending on mesoclimatic and surficial veneer influences.

Discussion

Till C is calcareous and medium textured, being derived primarily from carbonate and calcareous clastic strata. It is the most extensive of the three tills differentiated in

Banff and Jasper. The Goat (GT), Molar Pass (MP), Peyto Lake (PL), Patricia (PT), and Warwick (WW) Ecosections occur on moraines consisting of Till C. The Baker Creek 1 (BK1), Bryant 1 and 2 (BY1, BY2), Norquay 1 (NY1), and Panorama Ridge 1, 2, and 3 (PR1, PR2, PR3) Ecosites occur on moraines consisting of Till C. Calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) often shares contiguous glacial landforms with Till C on valley floors and benchlands. Consequently, both form the landforms of the Baker Creek 6 (BK6), Norquay 3 (NY3), and Panorama Ridge 4 (PR4) Ecosites. Till C, comprised predominantly of material derived from Mesozoic strata, dominates the Tyrrell (TR) and Snowflake (SF) Ecosections. Tills C and B are codominant in the moraines forming the Consolation Valley 1 (CV1) and Sphinx 3 (SX3) Ecosites. Till C is the subdominant genetic material unit of the landforms of the Sphinx 2 (SX2) Ecosite and is a minor constituent of the landforms of the Sphinx (SX1) Ecosite.

A dark colored phase of Till C is common in eastern regions of both Banff and Jasper. Its color (dark browns and grays to black) is attributed to incorporation of material from carbonaceous Mesozoic strata. Till C is normallly much lighter in color and ranges through the browns and yellowish browns to gray browns and grays.

Recent moraines, including the Miscellaneous Landscape M and the Warwick (WW) Ecosection, consist primarily of Till C. Existing glaciers are associated with the upper stratigraphic column of the Main Ranges subprovince. Their Neoglacial moraines are derived from the calcareous strata forming this column.

ICE CONTACT STRATIFIED GENETIC MATERIAL

Ice contact stratified drift is partially sorted material deposited by glacier ice but with concomitant and subsequent reworking, locally, by flowing and ponded glacial meltwater. The result is extreme vertical and lateral textural variability over short distances, except where coarse to medium grained source strata preclude the incorporation of abundant clay and silt sized particles. In essence, ice contact stratified drift encompasses an intimate, random mixture of morainal, glaciofluvial, and occasionally, glaciolacustrine sediments individually inseparable at a scale of 1:50,000. Unsorted, unstratified morainal material (till) is occasionally intimately associated with ice contact stratified drift, both are collectively considered glacial deposits as opposed to the proglacial materials, glaciofluvial and glaciolacustrine. Glaciofluvial terraces often adjoin ice contact stratified deposits and form adjacent landscape downslope on valley floors. Glaciolacustrine veneers often overlie ice contact stratified deposits.

Ice contact stratified drift forms moraine-like landforms near valley floors, on valley floor benchlands, and, occasionally, on lower valley wall slopes. This genetic material is most abundant in the lower reaches of valley systems, particularly of broader valleys, and hence is most extensive in the Montane and Lower Subalpine. Distribution is limited in the Upper Subalpine, very limited in the Alpine.

Hummocky, ridged, and inclined surface expressions are typical of ice contacted stratified deposits. Hummocky surfaces are most often of depositional origin, ridged surfaces may reflect underlying bedrock or depositional features. Outstanding depositional features include kettles, kames, and eskers. Differential erosion by ice margin streams has also contributed to irregular surface forms. Two types of inclined surfaces occur. Deposits on lower valley wall slopes are depositional with linear (straight), inclined surfaces reflecting underlying bedrock. Occasionally on this physiographic position, hummocky depositional surfaces are superimposed upon the inclined bedrock surfaces. The second type is erosional, encompassing the short stream bank scarps created by the down and sidecutting action of present and historical streams.

The most important modifying processes are channelling (Eroded modifier, C.S.S.C. 1978b) and gullying. These have resulted in differential erosion and, in the case of ice marginal channels, have contributed significantly to the irregular (ridged and hummocky) surface expressions. Failed slopes occur occasionally and also influence surface form. Other modifying processes, which influence primarily soil and vegetation development, include snow avalanching, sheet erosion, and soil creep. In some areas, ice contact stratified drift deposits are thinly mantled by other genetic materials, namely eolian, fluviolacustrine, glaciolacustrine, and organic.

Derivation of ice contact stratified deposits is associated with Pleistocene glaciation (Stalker 1963, 1969, McPherson 1970, Harris and Boydell 1972, Rutter 1972, Shaw 1972, Fox 1974, Roed 1975). Textural qualities are attributable, in part, to source bedrock lithology and, in part, to reworking of the glacial deposits by glacial meltwater. Calcareousness and reaction properties reflect source bedrock lithology. Two ice contact stratified units are identified in the Banff-Jasper Ecological Land Classification report. Separation is based primarily on chemical properties, secondarily on textural charcteristics, both reflecting different bedrock sources. The two units are: (1) noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) de-

rived primarily from medium to coarse grained, noncalcareous clastic strata ,and (2) calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) derived from medium to fine grained, calcareous clastic and carbonate strata.

ICE CONTACT STRATIFIED DRIFT A

Concept and Distribution

Modally, Ice Contact Stratified Drift A is noncalcareous (acidic), coarse textured, glacial drift that is derived from medium to coarse grained, noncalcareous clastic bedrock and has been partially reworked by flowing glacial meltwater. Its major source is the lower Cambrian Gog Group (quartzite) that dominates portions of the Main Ranges geologic subprovince. Ice Contact Stratified Drift A generally grades, upslope, into unsorted, unstratified, noncalcareous, coarse textured till (Till A).

Ice Contact Stratified Drift A is the least extensive of the two ice contact stratified units and occurs primarily in the Subalpine Ecoregion. The type area is the Blue Creek valley in northern Jasper where the unit dominates the valley floor benchlands and lower slopes. This valley is geologically dominated by the McNaughton Formation, a subdivision of the Gog Group. In a few areas the textural influence of medium to fine grained, noncalcareous, clastic bedrock (Miette Group slate and shale) is evident, the derivative being a variably textured variant of Ice Contact Stratified Drift A. This variant is of limited areal extent. Major known occurrences are located in the upper Miette River valley, in the Astoria River valley below Mt. Edith Cavell, and in the Bow River valley between Vermilion Pass and Eisenhower Junction. The last occurrence is described by Rutter (1972) as an ice contact fluvial complex featuring abandoned side glacial stream channels. The variably textured variant generally grades, upslope, into unsorted, unstratified, noncalcareous, medium textured till (Till B).

Surface Expression and Modifying Processes

Glacial landforms comprised of Ice Contact Stratified Drift A commonly exhibit hummocky and ridged surface expressions. These surfaces reflect deposition, localized bedrock control, and differential erosion by ice marginal streams. Slopes are complex and commonly range from 5 to 45%. Inclined surfaces are not common. In some areas, this hummocky and ridged terrain is bounded below by terraces consisting of noncalcareous, coarse textured glaciofluvial material (Glaciofluvial material A).

Channelling (Eroded modifier, C.S.S.C. 1978b) is the most important process that has affected landforms composed of Ice Contact Stratified Drift A. Ice marginal channels are common and contribute to slope complexity. The channels are randomly distributed, sinuous, and generally converge downvalley, emptying onto valley floors. Process status is considered inactive although some channels contain modern, intermittent streams. Several channels have been eroded deep enough to expose local water tables. High water tables plus stream activity have resulted in wetland localities contained in channel depressions between ridges and hummocks.

Textural Properties

Ice Contact Stratified Drift A is coarse textured, being comprised of about 60 to 100% sand, 0 to 10% clay, and 5 to 70% rounded to subrounded coarse fragments dominated by quartzites. Low silt and clay contents reflect the coarse to medium grained, source bedrock. The fine earth range falls within the sandy loam, loamy sand, and sand textural classes defined by C.S.S.C. (1978a). It is based on a very few analyzed samples, therefore was established by combining the modal textural ranges of noncalcareous, coarse textured till (Till A) plus noncalcareous, coarse textured glaciofluvial material (Glaciofluvial material A). Conceptually, Ice Contact Stratified Drift A is an intimate complex of these two genetic materials. Glaciolaucstrine sediment is a rare constituent. Vertical stratification occurs but is rather subtle. Lateral textural variability over short distances is greater than in the vertical direction but not to the extent that typifies calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B).

The variably textured variant of Ice Contact Stratified Drift A has the same textural variability as Ice Contact Stratified Drift B. Its major source is medium to fine grained, noncalcareous, clastic bedrock, namely the Miette Group. Hence, the glacial derivatives are generally medium textured (silt loam, loam, and sandy loam, like Till B) but locally reworked by flowing and ponded glacial meltwater creating coarse textured (sandy loam to sand) and fine textured (silty clay loam and silty clay) layers and pockets. Coarse fragment content in this variant ranges from 5 to 70% by volume.

Calcareousness and Reaction Properties

Modally, Ice Contact Stratified Drift A is noncalcareous and acid. There are insufficient analytical data to establish reaction class and pH ranges, therefore the ranges for noncalcareous, coarse textured till (Till A) are assumed to apply. These are extremely to medium acid with pH values of about 4.3 to 6.0. Small amounts of lime (<15% $CaCO_3$ equivalent) accompanied by higher pH (6.0 to 7.0) may occur at depth in some localities

(e.g. Athabasca River valley downstream from the Chaba River confluence). The soils, however, are deeply weathered with thick eluvial (Ae) horizons and have extremely to strongly acidic (pH 5.5 or less) sola including, specifically, the B and underlying horizons to a thickness of 25 cm.

Discussion

Ice Contact Stratified Drift A is derived primarily from quartzitic bedrock and is the least extensive of the two ice contact stratified material units. The Azure 1 (AZ1) and Topaz 2 (TZ2) Ecosites occur on glacial landforms comprised of Ice Contact Stratified Drift A. This material and noncalcareous, coarse textured glaciofluvial material (Glaciofluvial material A) are codominant in the Topaz 1 (TZ1) Ecosite. The variably textured variant of Ice Contact Stratified Drift A is an accessory geomorphic feature of the Cavell 1 (CA1) Ecosite. Both the modal and variant forms occur as accessory features of the Consolation Valley 1 (CV1) Ecosite. Minor occurrences of Ice Contact Stratified Drift A may be found in other Ecosites such as Cavell 2 and 4 (CA2, CA4), Larch Valley 3 (LV3), Moraine Lake 1 and 2 (ML1, ML2), and Sphinx 2 (SX2).

ICE CONTACT STRATIFIED DRIFT B

Concept and Distribution

Modally, Ice Contact Stratified Drift B is noncalcareous (neutral to alkaline), variably textured, glacial drift that is derived from medium to fine grained, calcareous clastic and carbonate bedrock and has been partially reworked by flowing and ponded glacial meltwater. Plate 4 shows an Ice Contact Stratified Drift B deposit in section located near the Mistaya Canyon bridge in Banff.

Ice Contact Stratified Drift B is the most extensive of the two ice contact stratified units and occurs primarily in the Subalpine and Montane Ecoregions. It is most often in the lower reaches of valley systems, particularly of broad valleys. It forms moraine-like landforms near valley floors, on valley floor benchlands, and, occasionally, on lower valley wall slopes.

Surface Expression and Modifying Processes

Glacial landforms comprised of Ice Contact Stratified Drift B commonly exhibit hummocky, ridged, and inclined surface expressions. Slopes are complex and simple and range from 5 to 70%. Hummocky surfaces are most often of depositional origin, but occasionally reflect bedrock control. Ridged surfaces may reflect underlying bedrock or depositional features. Outstanding depositional features include kettles, kames, and eskers. Differential erosion also contributes to irregular surface forms. Ice marginal channels are common in some localities. Small terraces occur occasionally.

Two types of inclined surfaces occur. Deposits on lower valley wall slopes are depositional, often with linear, inclined surfaces reflecting underlying bedrock. In some cases on this physiographic position, hummocky depositional surfaces occur on inclined bedrock surfaces. The second type is erosional and encompasses the short, sinuous, stream bank scarps created by the down- and sidecutting action of present and historical streams through glacial deposits that mantled valley floors.

Channelling (Eroded modifier, C.S.S.C. 1978b) and gullying are the most important processes that have affected landforms composed of Ice Contact Stratified Drift B. Ice marginal channels are common in a few localities and contribute to slope complexity. The channels are randomly distributed, sinuous, and generally converge downvalley, emptying onto valley floors. Process status is considered inactive although some channels contain modern, intermittent streams. These erosional features are not as common and extensive as on landforms of Ice Contact Stratified Drift A but, like those in the noncalcareous counterpart, some contain wetlands. Subparallel gullies oriented perpendicular to the contour characterize many of the more steeply sloping inclined surfaces, particularly the stream bank scarps. Process status may be active or inactive. Failed slopes occur occasionally and contribute to hummocky surface expressions.

Other modifying processes, which influence primarily soil and vegetation, include snow avalanching at higher elevations on valley walls and sheet erosion or soil creep on the steepest slopes. In some areas, other depositional processes have operated subsequent to glacial deposition, thereby creating eolian, fluviolacustrine, glaciolacustrine, and organic blankets and veneers that mantle the Ice Contact Stratified Drift B deposits. Of note are calcareous, medium textured eolian material (Eolian material A) mantling the landscape in the lower Athabasca and North Saskatchewan/Howse River valleys and calcareous, fine textured glaciolacustrine material (Glaciolacustrine material) occurring in pockets in the lower Spray, Mistaya, Rocky, and Snake Indian River valleys. Ice Contact Stratified Drift B generally grades, upslope, into unsorted, unstratified, calcareous, medium textured till (Till C), deposited as part of the same glacial event. In several areas, the hummocky and ridged terrain of Ice Contact Stratified Drift B is bounded below (downslope) by terraces consisting of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B).

Textural Properties

Ice Contact Stratified Drift B is variably textured. Extreme vertical and lateral textural variability over short distances is characteristic and attributable to its polygenetic depositional environments. The material originated as medium textured (silt loam, loam, and sandy loam, like Till C) glacial detritus derived from medium to fine grained strata. Local reworking by flowing glacial meltwater created coarse textured (sandy loam to sand) layers and pockets. Less often, silt- and clay-laden meltwater was locally ponded creating fine textured (silty clay loam and silty clay) layers and pockets. The overall result is a wide range in fine earth composition with sand content ranging from 0 to 100%, clay content from 0 to 50 or 60%. Rounded and subrounded coarse fragments also show vertical and lateral stratification and constitute 5 to 70%, by volume, of Ice Contact Stratified Drift B.

Calcareousness and Reaction Properties

Ice Contact Stratified Drift is strongly to extremely calcareous and neutral to mildly alkaline in reaction. Calcium carbonate equivalent content commonly ranges from 15 to 85%, pH values from 7.0 to 7.8. pH values >7.8 or lime content >85% are rare. However, a low lime phase, with carbonate content ranging from 1 to 15% and pH values from about 6.8 to 7.8, is important in some areas where noncalcareous clastic strata occur extensively. The area of note encompasses the middle Athabasca and lower Miette River valleys upstream from Jasper townsite. In this area, the low lime phases of Ice Contact Stratified Drift B and Till C are underlain by Miette Group strata.

The soils developed in Ice Contact Stratified Drift B, including the low lime phase, have thinner sola and higher reaction than those developed in Ice Contact Stratified Drift A. Soils developed in the calcareous material generally have medium acid to neutral (pH >5.5) lower sola including, specifically, the B horizon and underlying horizons to a thickness of 25 cm.

Discussion

Ice Contact Stratified Drift B is derived primarily from calcareous clastic and carbonate bedrock and is the most extensive of the two ice contact stratified material units. No Ecosection separations are based on this geomorphic unit in the Banff-Jasper Ecological Land Classification. Rather, it was included with Ecosections characterized by Till C moraines because the two geomorphic units are often intimately associated and form contiguous landscape, having shared glacial events. More importantly, they have similar surface expressions and are associated with similar soils and vegetation. However, Ice Contact Stratified Drift B is recognized at the Ecosite level in the taxonomy. The Baker Creek 4 (BK4), Bryant 4 (BY4), Norquay 3 (NY3) and Panorama Ridge 6 (PR6) Ecosites are dominated by glacial landforms consisting of Ice Contact Stratified Drift B. In the Baker Creek 6 (BK6), Panorama Ridge 4 (PR4), and Talbot 3 (TA3) Ecosites, this unit is codominant with Till C. Glacial materials of TA3 are overlain by blankets and veneers of calcareous, medium textured eolian material (Eolian material A). Ice Contact Stratified Drift B is an important accessory feature of the Goat 2 (GT2), Patricia 1, 3, 4, and 5 (PT1, PT3, PT4, PT5), and Consolation Valley 1 (CV1) Ecosites. Limited occurrences may be found in other Ecosites.

GLACIOFLUVIAL GENETIC MATERIAL

Glaciofluvial genetic material in Banff and Jasper is the deposit generated by flowing water whose volume and sediment load are principally controlled by melting glacier ice. These deposits have largely ceased aggrading with the retreat of the glacier, but some near present ice fronts are still actively aggrading. This usage differs from C.S.S.C. (1978b) in that herein glaciofluvial material is regarded as essentially proglacial. Material with similar characteristics, but having irregular surfaces and local extent indicating direct contact with glacier ice is considered part of ice contact stratified genetic material.

Glaciofluvial material originates from abnormally high flow rates in a watershed as generated by release of water stored in ablating icefields. Large volumes of melting ice are needed to produce a deposit of any extent. Deposition occurs where this meltwater encounters a valley floor with gentle grade. The resulting sediment overload is rapidly deposited, especially the coarser bedload, producing massive bedding. Much of the silt and clay fraction either remains in suspension or is easily eroded again, especially if it is not stabilized by vegetation. Thus, the resulting deposit is high in coarse fragment content and coarse textured. Diurnal fluctuation in flow during summer melting is also important to rapid aggradation, as daily falling water levels also produce sediment overload. Smith (1972) discusses some of these processes presently occurring at the confluence of the Alexandra and North Saskatchewan Rivers in Banff. Glaciofluvial material grades into fluvial material with increasing distance from the glacier as flow fluctuations and sediment load are less influenced by the melting ice. In these situations, sediment more typically is stratified and aggrades much less rapidly. Lakes within a river system often act as a buffer, separating glaciofluvial at the head from fluvial at the mouth (e.g. Peyto Lake). South of Saskatchewan Crossing, Banff pre-

sently has and probably historically had more attenuation of glaciofluvial conditions by lakes than Jasper and northern Banff. Portions of the Athabasca and North Saskatchewan drainages emanating from the Columbia and proximal icefields impart glaciofluvial-like characteristics to these rivers throughout their course in the parks, as no lakes buffer the flow and sediment load. In contrast, the Bow and Mistaya Rivers in Banff are fluvial systems despite the amount of ice feeding them, a result of loss of sediment to and flow regulation by lakes on tributaries and along their courses.

A different magnitude of activity is evident in the soils and especially vegetation between recent, well drained fluvial and glaciofluvial systems. On actively aggrading fluvial landforms, deposition is frequent enough to hold soil development to a minimum (e.g. Regosols, weakly developed Brunisols), while vegetation is often at climax (e.g. spruce forest). This indicates activity within the order of 10^2 yrs. On actively aggrading glaciofluvial landforms, Regosolic soils are the rule, but in this case vegetation is also held to incipient stages (e.g. herb mat, shrub thicket). This indicates activity within the order of $\leq 10^1$ yr. A trimline-like effect, particularly marked with trees, at the boundaries of presently active glaciofluvial areas is a distinctive trait usually not evident on active fluvial areas (Plate 5).

Glaciofluvial deposits are distributed throughout the parks on valley floors and lower benchlands, locations that generally occur in broad valleys. The frequency of occurrence and extent of deposits decrease with increasing elevation because the volume of ice up valley diminishes as the glacier terminus recedes upward. Source area becomes increasingly restricted with increasing elevation as well. Since the present ecological zonation is also elevationally influenced, a lesser percentage of each Ecoregion is occupied by glaciofluvial material from Montane to Alpine respectively.

The influence of source diversity and glacial contribution to stream deposits is evident from calcareousness properties of sediments from the present and ancestral Athabasca Rivers. In the vicinity of Jasper townsite, our samples from the glaciofluvial terraces are approximately 20% $CaCO_3$ equivalent, while sediment in the present stream bed is about 60%. This occurs despite the greater textural maturity of the more recent deposits. Reference to the geological map of Price and Mountjoy (1970a) indicates that the only extensive calcareous strata are at the extreme headwaters of this river and some of its tributaries, locations that also currently support icefields. Therefore a majority of sediment in the present Athabasca River must be derived from the very restricted occurrence of calcareous strata, probably through the agent of ice, and carried to its present location by meltwater. The sediment from the ancestral river shows a carbonate content more in keeping with the proportion of calcareous and noncalcareous bedrock in the drainage, indicating wider ice activity on diverse sources when material in the terraces was deposited by a closer ice front.

Glaciofluvial materials are marginally younger than, and often overlie, till and ice contact deposits of the same glacier, exposed during retreat. Highest terrace levels in an area are composed of the oldest glaciofluvial materials and formed closest to the retreating ice. Subsequent underfit streams incise into this unconsolidated material, generating terraces embracing a new valley flat having dimensions commensurate with the lesser flow. Glaciofluvial material often is buried by more recent fluvial material, especially on present fluvial fans. Eolian material in various thicknesses overlies most glaciofluvial material except in northern Jasper.

As previously discussed, coarse textures are chiefly governed by the depositional environment. However, a continuum of chemical properties from noncalcareous, acid, to highly calcareous, alkaline exist. For purposes of this Ecological Land Classification, this continuum was broken into two genetic material units. These are Glaciofluvial material A (essentially noncalcareous) and Glaciofluvial material B (calcareous), with characteristics as discussed below.

GLACIOFLUVIAL MATERIAL A

Concept and Distribution

Glaciofluvial material A is noncalcareous, coarse textured material deposited by glacial meltwater. It reflects almost exclusively noncalcareous original bedrock source strata, but is usually derived from a reworking of noncalcareous glacial till.

Glaciofluvial material A is absent from the Montane because the diversity of bedrock in the source area always includes calcareous strata. Lower Subalpine and Upper Subalpine occurrences are restricted to valleys in the Main Ranges which, especially around the glacier head, have walls made up of the Gog and/or Miette Groups. Glaciofluvial material A is therefore less extensive than Glaciofluvial material B, its calcareous counterpart.

Surface Expression and Modifying Processes

Terrace is the most common surface expression of Glaciofluvial material A. Slopes are complex, but a majority of any surface is made up of linear terrace treads with <5%

slope. Short risers between terrace levels are steeper, with slopes from 30 to 70%.

Evidence of abandoned channels (Eroded modifier, C.S.S.C. 1978b) is often present on the terrace treads, but these do not significantly affect material properties. Eolian veneers frequently mantle glaciofluvial deposits except in northern Jasper, resulting in medium textures in the upper sola developed on these landforms.

Textural Properties

Textures of Glaciofluvial material A are coarse, being strongly controlled by the high energy glacial meltwater which acted as a depositional agent. Also, materials derived from Gog Group strata are inherently low in clay. Sand is usually >60%, while clay is seldom >5%. These values fall within part of the sandy loam, loamy sand, and sand classes of C.S.S.C. (1978a). Bedding is often massive, but where stratification occurs textures fall within the coarse category.

The coarse fragment content range is 35 to 70% by volume, mainly subrounded gravels and cobbles. Surfaces are frequently very stony (C.S.S.C. 1978a), particularly in the absence of an eolian surface veneer. Some surfaces are lower in coarse fragments, indicating a waning stage of glaciofluvial activity, probably at some distance from the ice front.

Calcareousness and Reaction Properties

Glaciofluvial material A is usually noncalcareous, hence acid, ranging from extremely to medium acid (C.S.S.C. 1978a) with pH values 4.3 to 6.0. Where calcareous materials start to impart Glaciofluvial material B characteristics, separation of these materials is based on pH of the sola developed on them. Specifically Glaciofluvial material A produces sola with pH ≤5.5 to a depth of 25 cm below the top of the B horizon. This includes low lime glaciofluvial material with up to about 10% $CaCO_3$ equivalent. No presently active glaciofluvial material is Glaciofluvial material A because $CaCO_3$ equivalents are much greater than 10%.

Discussion

Glaciofluvial material A is less extensive than Glaciofluvial material B, its calcareous counterpart, and is a common constituent of the Topaz 1 (TZ1) Ecosite and plays a minor role in Topaz 2 (TZ2) and Azure 1 (AZ1). Locally, it may resemble ice contact stratified material, but in the latter, a landform encompassing a variety of materials, surfaces are irregular. Fluvial material is coarse textured and stratified, with a wider range of coarse fragment content than Glaciofluvial Material A.

GLACIOFLUVIAL MATERIAL B

Concept and Distribution

Glaciofluvial material B is calcareous, coarse textured material deposited by glacial meltwater. It reflects the presence of some calcareous strata in the original bedrock source, but is usually derived from a reworking of calcareous glacial till.

Glaciofluvial material B is distributed throughout the parks, because of the extent of calcareous sources and the small content of lime needed to make a sediment calcareous. It is the only glaciofluvial material occurring in the Front Ranges. It occurs in both stable and presently aggrading forms. All presently active glaciofluvial material is calcareous because icefields and large glaciers presently occur on calcareous bedrock of the upper stratigraphic column of the Main Ranges (refer to Glacier (GL) Miscellaneous Landscape).

Surface Expression and Modifying Processes

Terrace is the most common surface expression of stable Glaciofluvial material B. Slopes are complex, but a majority of any surface is made up of linear terrace treads with <5% slope. Short risers between terrace levels are steeper, with slopes from 30 to 70%. Active Glaciofluvial material B has both level and fan surface expressions that will be maintained until a decrease in flow occurs. These areas, with slopes <5%, are analagous to and probably in future will become terrace treads.

Evidence of abandoned channels (Eroded modifier, C.S.S.C. 1978b) is often present, but these do not significantly affect material properties. Eolian veneers frequently mantle stable glaciofluvial deposits except in northern Jasper, resulting in medium textures in the upper sola developed on these landforms.

Textural Properties

Textures of Glaciofluvial material B are coarse, being strongly controlled by the high energy glacial meltwater which acted as a depositional agent. Sand is usually >60%, while clay is seldom >5%. These values fall within part of the sandy loam, loamy sand, and sand classes of C.S.S.C. (1978a). Bedding is often massive, but where stratification occurs textures fall within the coarse category. Fig. 15 illustrates textural variation of selected C horizons of all pedons sampled on Glaciofluvial material B.

Coarse fragment content range is 35 to 70% by volume, mainly subrounded gravels and cobbles. Surfaces are frequently very stony (C.S.S.C. 1978a), particularly in the absence

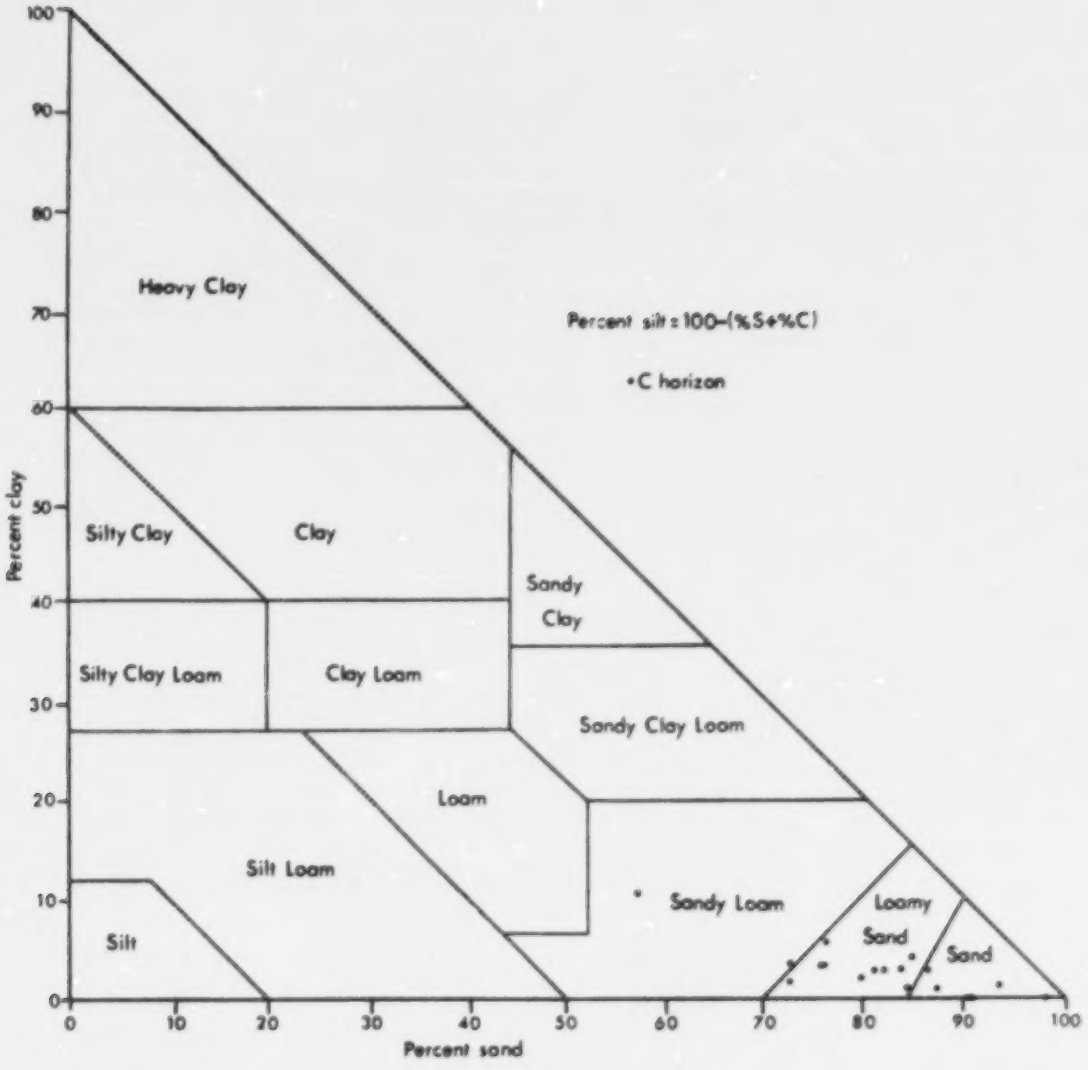

Figure 15 Textural variation among selected C horizons of all pedons sampled on calcareous, coarse textured glaciofluvial material (Glaciofluvial material B).

of an eolian surface veneer. Some surfaces are lower in coarse fragments, indicating a waning stage of glaciofluvial activity, probably at some distance from the ice front.

Calcareousness and Reaction Properties

Glaciofluvial material B is calcareous, hence neutral to moderately alkaline in reaction with pH values 7.0 to 8.0. Where low lime calcareous material with characteristics close to those of Glaciofluvial material A occurs, separation is based on pH of the sola developed on them. Specifically, Glaciofluvial material B produces sola with pH >5.5 within a depth of 25 cm below the top of the B horizon. This occurs with up to approximately 10% $CaCO_3$ equivalent. All presently active glaciofluvial material with Regosolic soils is classed as Glaciofluvial material B because it invariably has >10% $CaCO_3$ equivalent.

Discussion

Glaciofluvial material B is more extensive than Glaciofluvial material A, its noncalcareous counterpart, and is the principal genetic material of the stream channel (SC) Miscellaneous Landscape and of the Athabasca (AT), Bow Valley (BV) and Nigel (NG) Ecosections. Locally, it may resemble ice contact stratified material, but in the latter, a landform encompassing various materials, sur-

faces are irregular and materials are of variable texture. Boulders, absent in Glaciofluvial material B are often present in gravelly ice contact stratified material. Fluvial material is coarse textured and stratified, with a wider range of coarse fragment content.

FLUVIAL GENETIC MATERIAL

Fluvial (alluvial) material encompasses sediment deposited primarily by nonglacial flowing water. The distinction between glacial and nonglacial flow regimes is rather vague, particularly in a historical sense. Thus, it is quite possible that present fluvial landscape originated in glaciofluvial environments that changed over time, by glacial retreat and accompanying stream channel and sediment load alteration, to fluvial systems. Some stream floodplains (e.g. the lower Athabasca River valley floor in eastern Jasper), although mapped as fluvial landscape, are still aggrading, the sediment being transported primarily by glacial meltwater. These fluvial-glacial sediments are often interbedded with and locally supplanted by calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) on floodplains. Fitting neither the fluvial nor lacustrine definitions (C.S.S.C. 1978b), these fluviolacustrine deposits share the floodplain depositional environment, being restricted to ponded backwater localities that were or are episodically inundated by slowly moving, nearly stagnant, silt-laden waters. The toes of many fans and aprons are thinly mantled by altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) derived by sheet erosion and washing of upslope sediments.

Fluvial landscape is most abundant along valley floors including benchlands. Two distinct surface form groups, both with linear (simple) slopes, are characteristic. Level plains (floodplains), with slopes ranging from 0 to 2%, contain the major streams that formed them. Fans and aprons occur on gentle slopes along the toes of steeper slopes from which their sediments originated. These are especially extensive below gullied moraine and avalanched slopes on valley walls. Surface slopes of fans and aprons are generally concave and range from 2 to 45%. The steepest segments include the apexes, the gentlest slopes occur at the toes. Fluvial materials also exist as veneers and blankets in some cirque basin, col, shoulder, and valley floor localities. Here surface expressions reflect those of underlying material and may be irregular (complex). Weakly expressed terracing (risers <1 m) occurs on some fluvial floodplains.

The causes of stream deposition are similar on all fluvial landforms and involve the loss of transporting power resulting from a decrease in stream velocity. This is produced by a decrease in stream gradient, an increase in spread of stream waters, obstructions to flow, and a decrease in water volume (Thornbury 1954).

Patterns of deposition differ slightly on floodplain versus fan and apron forms. Stream braiding and meandering distribute sediment on level floodplains. Thornbury (1954), Leopold et al. (1964), and Smith (1972) discuss depositional processes and features on floodplains. These are shared by glaciofluvial flow regimes and include deposition of the finer textured fluviolacustrine materials of backwater reaches. Fluvial fan and apron development involves two contrasting processes. Construction by distributary streams, with most deposition occurring in and beside the migrating channels (washes) during flood episodes, is common (Engeln 1942, Thornbury 1954, McPherson and Hirst 1972, Roed and Wasylyk 1973). Mudflows are also important to varying degrees in fan and apron construction (Leopold et al. 1964, Winder 1965, McPherson and Hirst 1972, Owens 1972, Russell 1972, Roed and Wasylyk 1973). An example of recent mudflow activity occurred in the Bow River valley near Hector Lake in late August of 1977. Debris, accumulated in stream channels on the slopes below Mt. Hector, was dumped onto Highway 93.

Textural qualities differ somewhat between water course and mudflow deposition. Deposits associated with stream channel sedimentation are moderately to well sorted, vertically stratified, and variable across the landscape. The fine earth fraction commonly contains 15 to 90% sand and 0 to 25% clay; uniformity is present only as thin, randomly distributed layers and lenses. Rounded and subrounded coarse fragments, predominantly of gravel size, are distributed in like manner and range from 0 to 70%, by volume, of fluvial deposits. Thus, for convenience, fluvial materials are considered to be coarse textured and stratified. Amounts and grain size distribution of material transported to aggrading fluvial landscape are controlled by stream velocity, sediment load, and bedload. These are greatest during flood episodes, particularly following spring melt. Distribution of these sediments across fluvial landcape is controlled, in part, by local water velocity. The coarsest material, transported as bedload, gradually fills the channels; the finer material is deposited between channels during bank overflow. Over time the channel positions shift, thereby creating stratified deposits. Additionally, fans and aprons built by stream channel sedimentation tend to be coarser textured at their apexes than along their toes (Thornbury 1954, McPherson and Hirst 1972).

Mudflow deposits of fluvial fans and aprons are poorly sorted and uniformly textured with little or no stratification (Winder 1965, Roed and Wasylyk 1973). Coarse fragments range from gravels to boulders (Winder 1965) with

varying degrees of roundness. Thus, mudflow deposits are similar to their source materials whereas stream channel sediments do not resemble, texturally, source materials.

Linear (regular) slopes of many fluvial landforms are subtly broken by active and abandoned channels (Eroded modifier, C.S.S.C. 1978b). These are usually bounded by natural levees constructed by bank overflow during flood episodes. Textures of levee material, on existing surfaces, are generally intermediate between the coarse textured channels and the finer textured interchannel localities.

Fluvial landscape probably began developing immediately following glacial retreat, hence the speculation that the initial landforms are of glaciofluvial origin. Dating of buried volcanic ash layers (McPherson and Hirst 1972, Smith 1972, Roed and Wasylyk 1973) and observations on soil development in fluvial deposits indicate that ages of present fluvial surfaces and aggradation rates over time are highly variable. The youngest surfaces lack incised, well defined, stream channels, having instead several, shallow, often poorly defined distributary or braided channels that are level with or slightly higher than surrounding fluvial landscape (McPherson and Hirst 1972). These actively aggrading surfaces range in size from narrow strips adjacent to streams to domination of entire fluvial landforms. Soils associated with active aggradation are Regosolic and have poorly developed or absent surface organic layers.

Inactive fluvial surfaces are defined by Roed and Wasylyk (1973) as having well incised stream channels. Soil development on the surfaces surrounding the channels indicate relative age. Recent surfaces have Regosolic soils with thin surface accumulations of organic material. Older surfaces (i.e. 10^3 years and more), have B horizon development. However, cataclysmic fluvial deposition is unpredictable and can interupt the development of established soil horizons. The same age variability applies to fluvial landforms comprised predominantly of mudflow debris.

Fluvial landforms in Banff and Jasper are derived from diverse areas encompassing several other unconsolidated mineral genetic materials and various bedrock strata. As previously discussed, textures are mainly governed by depositional processes, but a continuum of chemical properties from noncalcareous, acid to highly calcareous, alkaline exists. For the purposes of Ecological Land Classification, this continuum was divided and organized to identify two fluvial material units. These are: noncalcareous, coarse, stratified fluvial material (Fluvial material A), derived from noncalcareous, unconsolidated mineral materials and noncalcareous bedrock; and calcareous, coarse, stratified fluvial material (Fluvial material B), derived from calcareous, unconsolidated, mineral materials and calcareous bedrock.

FLUVIAL MATERIAL A

Concept and Distribution

Modally, Fluvial material A is noncalcareous (acidic), coarse textured and stratified sediment deposited primarily by nonglacial flowing water and derived from noncalcareous, unconsolidated and consolidated materials. It is the least extensive of the two fluvial units because the noncalcareous source materials are less extensive than their calcareous counterparts. Distribution is greatest in the Main Ranges subprovince in areas dominated by Miette and Gog Group strata. Physiographic position (valley floors) within the Main Ranges structural setting places most occurrences in the Lower Subalpine portion of the Subalpine Ecoregion. Fluvial material A also occurs locally in areas dominated by Mesozoic strata. Sporadic Upper Subalpine and Alpine occurrences are related to subdued mountain topography (Mesozoic and Precambrian strata). Fluvial material A occurrences are very limited in the Montane Ecoregion.

Surface Expression and Modifying Processes

Fans and aprons are the most common surface expressions of Fluvial material A. These are generally concave and range from 2 to 45% slope. Level floodplain occurrences are limited, but dominate a few tracts. Veneers and blankets also occur occasionally, usually overlying morainal landforms.

Active and abandoned channels plus their natural levees are the most common modifying features. Avalanching and, at high elevations, solifluction occur but their effects on landform are negligible.

Textural Properties

Fluvial material A textures conform to the range (15-90% sand, 0-25% clay, 0-70% coarse fragments by volume) defined for the fluvial genetic material class discussed above. Water course deposits are stratified, mudflow deposits are not, unless considered as single layers within a polygenetic fluvial landform. In several instances, slates and shales dominate the coarse fragment fraction, particularly of mudflow layers derived from noncalcareous, medium textured till (Till B) or noncalcareous, medium textured colluvium (Colluvium B) sources.

Calcareousness and Reaction Properties

Fluvial material A is usually noncalcareous and acid, ranging from extremely to medium acid (C.S.S.C. 1978a) with pH values of about 4.3 to 6.0. Considering the diversity of source materials imparting characteristics to

any one fluvial landform, weakly calcareous mixtures (1-5% CaCO3 equivalent, pH 6.0-7.0) of Fluvial material A and calcareous, coarse, stratified fluvial material (Fluvial material B) are common. In some cases (e.g. Louise Creek fan) Fluvial materials A and B are interbedded, with Fluvial material A tending to dominate the present surface. Soil development is considered, where necessary, to separate weakly calcareous mixtures into Fluvial material A or B for mapping purposes, (i.e. Verdant (VD) versus Altrude (AL) Ecosections). Fluvial material A, including its low lime phase, is dominated by soils with extremely to strongly acidic (pH 5.5 or less) sola including, specifically, the B and underlying horizons to a thickness of 25 cm. Soils developed in the low lime phase of Fluvial material B generally have medium acid to neutral (pH >5.5) lower sola, provided pedogenic horizonation has occurred.

Discussion

Noncalcareous, coarse, stratified fluvial material (Fluvial material A) is the least extensive of the two fluvial material units. It dominates the fluvial landforms of the Verdant (VD) Ecosection and some tracts of the Cyclone 1 (CN1), Hector 1 (HC1), Hector 4 (HC4), Mosquito 1 (MQ1), Katherine 1 (KA1), and Num-Ti-Jah 2 (NT2) Ecosites. It is a minor constituent of the Hillsdale 1 (HD1) and Hillsdale 3 (HD3) Ecosites.

Thin veneers of altered medium textured eolian material (Eolian material B) and altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) occasionally overlie Fluvial material A. At low elevations (e.g. the Lower Subalpine) Regosolic soils are not abundant on this geomorphic unit. At higher elevations, they occur and are associated with recent aggradation or modifying processes such as solifluction. A dark colored phase, attributed to incorporation of carbonaceous Mesozoic material, occurs in eastern areas.

FLUVIAL MATERIAL B

Concept and Distribution

Modally, Fluvial material B is calcareous (neutral to mildly alkaline), coarse textured and stratified sediment deposited primarily by nonglacial flowing water and derived from calcareous, unconsolidated and consolidated materials. It is the most extensive of the two fluvial units because the calcareous source materials are more extensive than their noncalcareous counterparts. Also, only a small percentage of calcareous material within the sediment is necessary to produce Fluvial material B. It is common, primarily on valley floors and benchlands, throughout all areas and Ecoregions of Banff and Jasper. It is most extensive in the Montane and Lower Subalpine.

Surface Expression and Modifying Processes

Fans, aprons, and level floodplains are the most common surface expressions of Fluvial material B. Fans and aprons are generally concave from top to bottom and convex parallel to the slope and range from 2 to 45% slope. Level floodplains have linear slopes ranging from 0 to 2%. Veneers and blankets, usually overlying morainal landforms, also occur occasionally.

Active and abandoned channels plus their natural levees are the most common modifying features. Avalanching and, at high elevations, solifluction occur but their effects on landforms are negligible.

Textural Properties

Fluvial material A textures conform to the range (15-90% sand, 0-25% clay, 0-70% coarse fragments by volume) defined for the fluvial genetic material class discussed above. Water course deposits are stratified, mudflow deposits are not, unless considered as single layers within a polygenetic fluvial landform.

Calcareousness and Reaction Properties

Fluvial material B is usually calcareous and neutral to moderately alkaline in reaction. Calcium carbonate equivalent content commonly ranges from 5 to 85%, pH values from 7.0 to 8.0. Considering the diversity of source materials imparting characteristics to any one fluvial landform, weakly calcareous mixtures (1-5% $CaCO_3$ equivalent, pH 6.0-7.0) of Fluvial material B and noncalcareous, coarse, stratified fluvial material (Fluvial material A) are common. In some cases, the two genetic material units are interbedded. Soil development is considered, where necessary, to separate weakly calcareous mixtures into Fluvial material A or B for mapping purposes, (e.g. Altrude (AL) versus Verdant (VD) Ecosections). Fluvial material B, including its low lime phase, is dominated by soils with medium acid to neutral (pH >5.5) sola, including, specifically, the B and underlying horizons to a thickness of 25 cm. If Regosolic or wet soils are dominant, the distinction is not important. Soils developed in the low lime phase of Fluvial material A generally have extremely to strongly acidic (pH 5.5 or less) sola.

Discussion

Calcareous, coarse, stratified fluvial material (Fluvial material B) is the more extensive of the two fluvial genetic material units. It dominates the Altrude (AL), Hillsdale (HD) and Fireside (FR) Ecosections and the Pipestone 1, 2, 3, 6, and 7 (PP1, PP2, PP3, PP6, PP7) Ecosites. It is the most abundant and extensive constituent of the Cyclone 1 (CN1), Hector 1 (HC1), Hector 4 (HC4), Katherine 1 (KA1),

Mosquito 1 (MQ1), and Num-Ti-Jah 2 (NT2) Ecosites. Fluvial material B and calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) are co-dominant in the Vermilion Lakes 3, 4, and 5 (VL3, VL4, VL5) Ecosites. Fluviolacustrine material B often overlies, interbeds with, and locally supplants Fluvial material B on some floodplains. Altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) and, occasionally, altered medium textured eolian material (Eolian material B) thinly mantle Fluvial material B on some fans and aprons. Fluviolacustrine material A is especially common on toe positions. Calcareous, medium textured eolian material (Eolian material A), in some cases partially reworked by fluvial action, mantles some Fluvial material B landforms in the lower Athabasca River valley. A dark colored phase of Fluvial material B, attributed to incorporation of carbonaceous Mesozoic material, occurs in eastern regions of both parks.

FLUVIOLACUSTRINE GENETIC MATERIAL

Fluviolacustrine material encompasses relatively fine grained sediments deposited by slowly moving water, both glacial and nonglacial. Although defined as sediment deposited under alternating or overlapping fluvial and lacustrine conditions (Gary et al. 1972), floodplain fluviolacustrine deposits in Banff and Jasper are intimately associated with fluvial and glaciofluvial deposits and share their landforms. The second type is considered to be slope wash sediment. Consequently, fluviolacustrine material is considered to represent low energy deposition in fluvial systems.

By its textural characteristics, fluviolacustrine material does not fit the fluvial definition given by C.S.S.C. (1978b). It displays vertical and lateral textural variability and is only uniformly textured in thin layers and lenses. High contents of silt and/or clay are characteristic, hence this genetic material is conveniently labelled fine, stratified. Sand content commonly ranges from about 0 to 20%, clay content from 10 to 50%. This range includes all or parts of the silt, silt loam, silty clay loam, and silty clay textural classes as defined by C.S.S.C. (1978a). Coarse fragments are usually absent but may range to 5%.

The textural range of fluviolacustrine material overlaps that of glaciolacustrine material. Textural stratification and lateral variability is one feature differentiating fluviolacustrine sediment from the more uniform glaciolacustrine deposits. Secondly, fluviolacustrine material has a wide range of bulk density (0.7-1.9 g/cm^3 based on a few analyses) and shows massive structure. Glaciolacustrine material is typically dense with varving or pseudo subangular blocky structure. Thirdly, thin, fibrous, silt-and clay-laden, organic layers and pockets are common constituents of fluviolacustrine deposits, particularly on floodplains. Mineral plus organic stratification is rare in glaciolacustrine deposits. Surface form and geomorphic relationships constitute a fourth distinguishing feature.

Glaciolacustrine material occurs in former lake basins and mantles, as blankets and veneers, gently sloping glacial landforms of valley floor benchlands. Fluviolacustrine sediment occurs in two distinct geomorphic environments, neither recognizable as lake basins. The thickest deposits occur on present and former backwaters of valley floor floodplains where they overlie, interbed with, and locally supplant fluvial and glaciofluvial deposits. The second type occurs as thin (<30 cm), discontinuous veneers mantling glacial and fluvial landforms with a variety of surface expressions and slopes ranging to about 30%. These are derived locally by sheet erosion of surrounding materials.

Two fluviolacustrine material units are identified in Banff and Jasper. Differentiation is based on the distinctive geomorphic environments outlined above and on chemical characteristics. Altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) encompasses, primarily, slope wash sediment with altered chemical properties that reflect pedogenic processes. Calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) encompasses calcareous sediment on backwater portions of floodplains.

FLUVIOLACUSTRINE MATERIAL A

Concept and Distribution

Modally, Fluviolacustrine material A encompasses fine textured and stratified, chemically altered, slope wash sediment deposited by nonglacial, unconfined water flow. This material occurs as thin (usually <30 cm), mineral surface veneers but includes the noncalcareous, floodplain plus slopewash sediments of the Num-Ti-Jah 3 (NT3) Ecosite. In essence, Fluviolacustrine material A can be considered as the product of the sheet erosion process that modifies other genetic materials.

Source areas for Fluviolacustrine material A are local and include adjacent and shared landforms composed of morainal, colluvial, glaciolacustrine, and fluvial genetic materials. In many areas, eolian veneers, especially altered, medium textured eolian material (Eolian material B), have been redeposited as Fluviolacustrine material A. Deposition generally occurs downslope on gentler slopes or where established vegetation traps sediment. The resulting veneers commonly mantle morainal, glaciolacustrine, and fluvial landforms occurring in physiographic positions that receive high amounts of surface runoff. These

positions include shoulders and valley, cirque, and col floors and lower slopes. Veneers of Fluviolacustrine material A are most extensive on wet (imperfectly to very poorly drained) landscape and occur in all Ecoregions. Process status may be active or inactive with active aggradation occurring locally on wet landscape.

Surface Expression and Modifying Processes

Fluviolacustrine material A occurs most extensively as thin (usually <30 cm), discontinuous veneers mantling morainal, glaciolacustrine, and fluvial landscape. Surface expression remains that of the underlying morainal (inclined, hummocky, and ridged), glaciolacustrine (ridged, hummocky, and undulating), and fluvial (fan and apron) landforms. Slopes commonly range from 0 to 30%. The combination floodplain plus slope wash sediment characterizing the Num-Ti-Jah 3 (NT3) Ecosite is thicker than normal and forms level floodplains with gently inclined margins. Processes that modify fluviolacustrine veneers include wind throw of trees and, at high elevations, solifluction or cryoturbation. These processes affect surfaces and usually mix Fluviolacustrine material A with underlying materials. Floodplain deposits often have a few shallow channels (Eroded modifier, C.S.S.C. 1978b) with their slightly elevated natural levees.

Textural Properties

Fluviolacustrine material A is fine textured and stratified. High contents of silt and/or clay are characteristic. Sand content commonly ranges from 0 to 20%, clay content from 15 to 50%. Coarse fragments are usually absent but may range to 5% by volume. These are generally introduced by mixing processes such as solifluction.

Textural variation among selected A, B, and C horizon samples of Fluviolacustrine material A is shown in Fig. 16. It is assumed the pedogenic alteration has had minor effects on textural qualities of A and B horizons. Fluviolacustrine material A is slightly finer textured than Fluviolacustrine material B, but its textural range overlaps that of glaciolacustrine sediment. Landscape position, stratification, structure, and bulk density differentiate Fluviolacustrine material A from Glaciolacustrine material, as discussed previously.

In many cases, Fluviolacustrine material A consists of reworked and redeposited, altered, medium textured eolian material (Eolian material B). Consequently, they resemble one another, both having high silt content, low bulk density (about 0.5 to 1.5 g/cm^3 for a few measured samples), and similar soil development (pedogenic alteration). However, Fluviolacustrine material A normally has higher clay content as a result of the reworking.

Calcareousness and Reaction Properties

Chemical properties of Fluviolacustrine material A are described as altered for two reasons. First, this sediment originated as an erosional product of unconsolidated mineral surfaces that were exposed to weathering (pedogenic) processes over varying lengths of time. Secondly and more important, most Fluviolacustrine material A veneers comprise the mineral surface of soils where pedogenic weathering is the strongest. With sufficiently long periods of stability, leaching of carbonate and acidification occur during A and B horizon development. Consequently, the original qualities are unknown. Only sediment comprising the landforms of the Num-Ti-Jah 3 (NT3) Ecosite are known to have originated from dominantly noncalcareous sources. Recent and aggrading Fluviolacustrine material A of some fluvial fans and aprons is occasionally calcareous and alkaline.

Fluviolacustrine material A comprised dominantly of reworked, altered, medium textured eolian material (Eolian material B) has inherited the latter's primary mineral constituents. Soils developed in the two materials are similar, having strongly developed B horizons with high pyrophosphate-extractable iron and aluminum contents and, under certain climatic, vegetational, and moisture regimes, high humus contents.

Discussion

Altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) occurs extensively, thinly mantling other genetic material landforms, especially under wet conditions. Unusually thick deposits dominate the Num-Ti-Jah 3 (NT3) Ecosite. Fluvio- material A veneers overlying morainal deposits form the subdominant landform of the Sphinx (SX) Ecosection. It is a minor constituent of numerous other Ecosites.

FLUVIOLACUSTRINE MATERIAL B

Concept and Distribution

Modally, Fluviolacustrine material B encompasses calcareous, fine textured and stratified sediment deposited on backwater portions of floodplains by ponding of mainly glacial waters. It is the thickest and most stratified of the two fluviolacustrine material units and is confined to broad, valley floor floodplains where it overlies, interbeds with, and locally supplants fluvial and glaciofluvial sediments. A few backwater floodplains are dominated by Fluviolacustrine material B. Delta-like floodplains at the heads of lakes (e.g. upper Waterfowl Lake in Banff, Smith 1975) are included in the geomorphic environments that produce these deposits. Fluviolacustrine material B is most abundant in the Montane and Lower Subalpine.

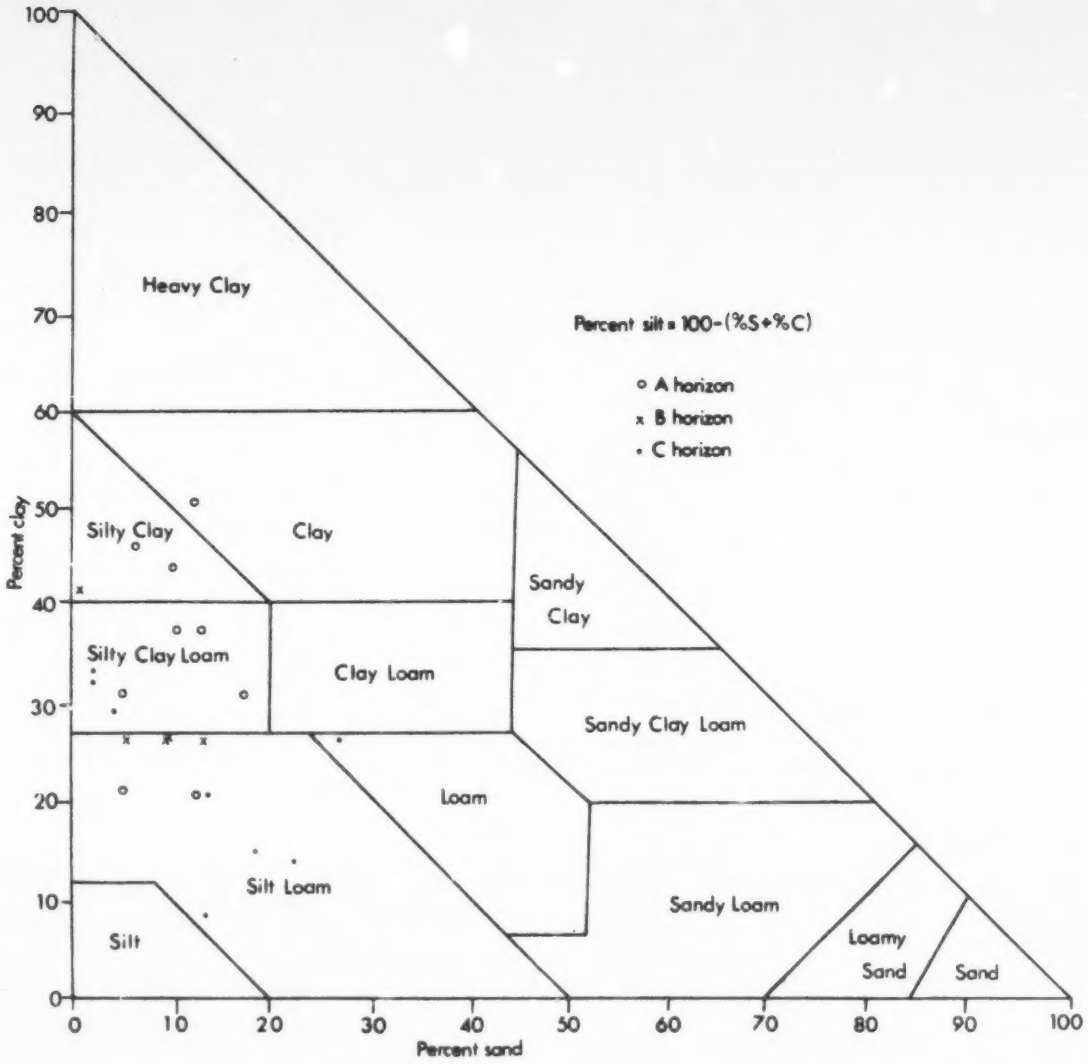

Figure 16 Textural variation among selected A, B, and C horizon samples of altered, fine textured, stratified fluviolacustrine material (Fluviolacustrine material A).

Ponding of silt-laden glacial streams on lake-head deltas and behind river channel constrictions (natural dams) promotes aggradation by siltation. Large gravelly fans produced by tributary streams often constrict major river channels, creating backwater floodplains upstream from the constrictions. Parts of the Alexandra and North Saskatchewan River floodplains are excellent examples (Smith 1972). Bedrock spurs (e.g. the bedrock ridge east of Bedson Ridge at Jasper's East Gate) and mantled, bedrock remnant landforms (e.g. Banff's Tunnel Mountain) aid river channel constriction.

Fluviolacustrine floodplains contain numerous distributary stream channels. Maximum deposition occurs during flood episodes with sediment-laden waters overflowing channel banks. Consequently, textures become progressively finer away from channels. Channel migration over time creates stratification. During low sediment cycles, moss and sedge vegetation becomes established but eventually gets buried by subsequent depositional events. Hence, Fluviolacustrine material B often contains thin layers of fibrous, silt- and clay- laden organic material. Thickness of Fluviolacustrine material B is probably quite variable. Smith (1972) reports up to 7.5 m of backwater floodplain sediment in his North Saskatchewan River study area. Underlying sediment is thought to be glaciofluvial sand and gravel on river floodplains, glaciolacustrine clays and silts on lake-head deltas.

In many areas, Fuviolacustrine material B is actively aggrading as evidenced by soils lacking surface organic layers and vegetation with poorly developed moss layers. The Hector 2 (HC2) Ecosite encompasses actively aggrading fluviolacustrine floodplains. Sedimentation on Vermilion Lakes 1 (VL1) tracts in the lower Athabasca River valley is recent and active. Some floodplains are presently inundated much of the year but by waters with low sediment loads (e.g. VL1 tracts near Banff townsite). Hence sedimentation no longer occurs and organic materials (peat) are accumulating beneath well developed moss and sedge layers.

Surface Expression and Modifying Processes

Fluviolacustrine material B is confined to level floodplains including delta-like areas of lake-heads. Slopes commonly range from 0 to 1%. Slope continuity is frequently broken by numerous, shallow, abandoned and active stream channels meandering across the landscape (Eroded modifier, C.S.S.C. 1978b). Gently sloping, slightly elevated levees border the channels.

Textural Properties

Fluviolacustrine material B is fine textured and stratified. High contents of silt and/or clay are characteristic. Sand content commonly ranges from 0 to 20%, clay content from 10 to 40%. Coarse fragments are usually absent but may range to 5% by volume.

Textural variation among selected A and C horizon samples of Fluviolacustrine material B is shown in Fig. 17. It is assumed that pedogenic alteration has had little effect on textural characteristics of A horizons. Although Fluviolacustrine material B has slighty less clay than Fluviolacustrine material A, its textural range still partially overlaps that of glaciolacustrine sediment. Landscape position and landform, stratification, intimate relationships to fluvial and glaciofluvial deposits, bulk density, structure, and organic material incorporation differentiate Fluviolacustrine material B from Glaciolacustrine material, as discussed under the Fluviolacustrine genetic material section. A silty, coarse fragment-free phase of Fluvial material B texturally overlaps silty (low clay content) Fluviolacustrine material B. They often occur together locally and distinguishing the two is usually unnecessary in such situations. Textural overlap is normal considering that the two units are often interbedded or contiguous and that each represents deposition in a part of the dynamic fluvial environment.

Calcareousness and Reaction Properties

Modally, Fluviolacustrine material B is moderately to extremely calcareous and neutral to mildly alkaline in reaction. Calcium carbonate equivalent content commonly ranges from 5 to 70%, pH values from 6.8 to 7.8. Source materials, usually fluvial, glaciofluvial, and morainal deposits upstream, are diverse and far removed from depositional localities but always include landform deposits bearing lime.

Discussion

Calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) occurs extensively on fluvial and glaciofluvial floodplains subject to episodic flooding and affected by high water tables. The Hector 2 (HC2) and Vermilion Lakes 1 (VL1) Ecosites are dominated by level floodplains comprised of Fluviolacustrine material B. Fluviolacustrine material B and the coarse fragment-free phase of Fluvial material B dominate the upper 1 to 2 m or more of the level landforms typifying the Vermilion Lakes 3, 4, and 5 (VL3, VL4, VL5) Ecosites. The floodplains of the Hector 1 (HC1), Hector 4 (HC4), and Num-Ti-Jah 2 (NT2) Ecosites often contain layers of Fluviolacustrine material B. It is a minor constituent of drier, level, fluvial landforms common to the Hillsdale (HD), Altrude (AL), and Pipestone (PP) Ecosections.

GLACIOLACUSTRINE GENETIC MATERIAL

Glaciolacustrine material encompasses fine-grained sediment deposited in proglacial lake environments. This sediment is composed of suspended material brought by meltwater streams flowing into lakes bordering glaciers (Gary et al. 1972). In Banff and Jasper glaciolacustrine material commonly overlies glacial landforms.

The textural range of glaciolacustrine material overlaps that of fluviolacustrine material. Textural stratification and lateral variability is one feature differentiating fluviolacustrine sediments from the more uniform glaciolacustrine deposits. Glaciolacustrine material is typically dense with varving and pseudo subangular blocky structure whereas fluviolacustrine material has a wide range of bulk density and shows massive structure. Fluviolacustrine material often has mineral plus organic layers; buried organic layers are absent from glaciolacustrine deposits. Fluviolacustrine deposits are not restricted to lake basins.

Glaciolacustrine material occurs in former lake basins and mantles, as blankets and veneers, gently sloping glacial landforms of valley floors and benchlands. In Banff and Jasper most of the glaciolacustrine deposits are located in the lower drainages of some tributary valleys of the Athabasca, North Saskatchewan, and Bow River valleys. Speculation

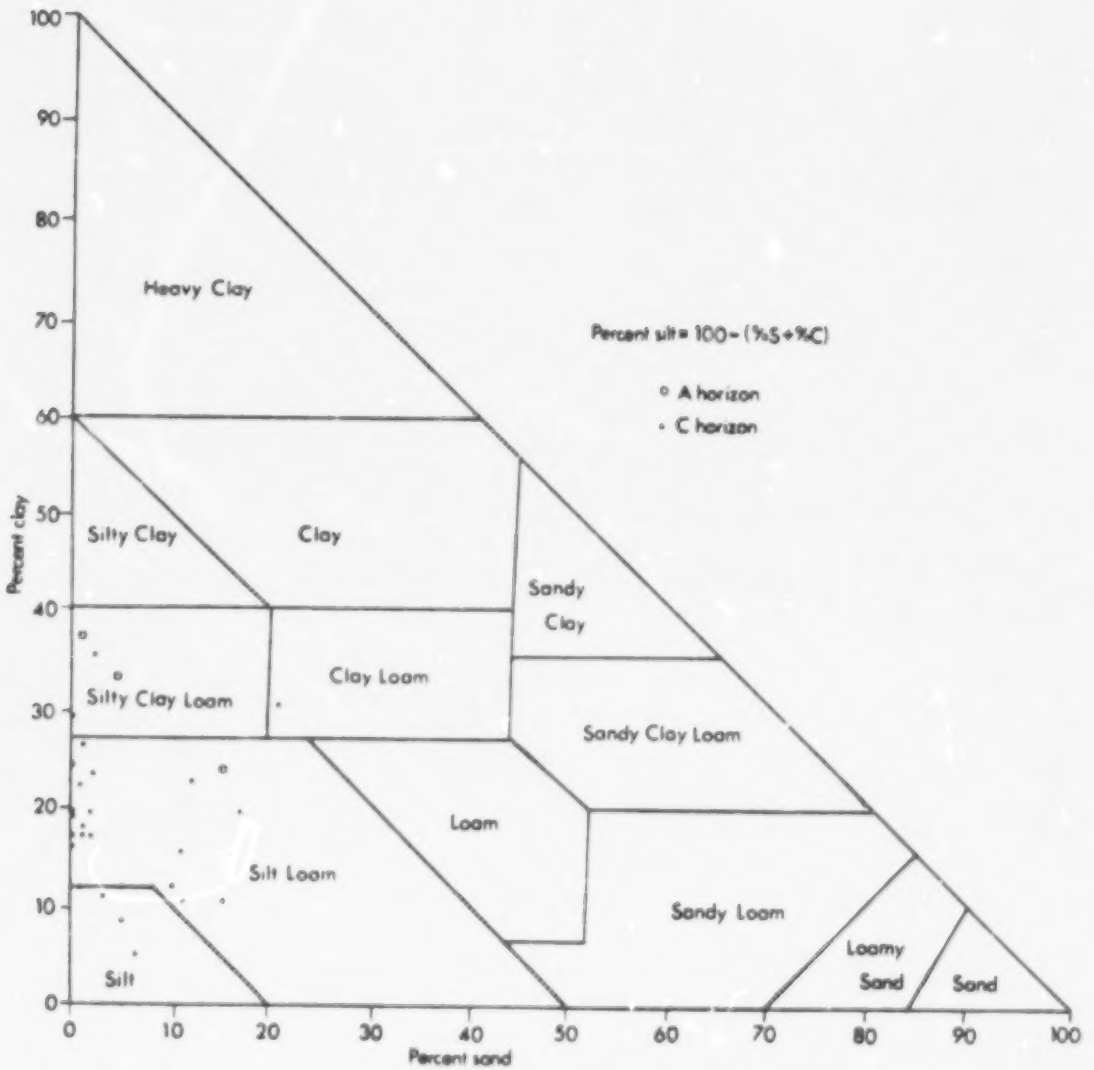

Figure 17 Textural variation among selected A and C horizon samples of calcareous, fine textured, stratified fluviolacustrine material (Fluviolacustrine material B).

is that glaciers in these major valleys dammed the tributaries. Only one glaciolacustrine unit is described in Banff and Jasper. This unit is fine textured and calcareous.

GLACIOLACUSTRINE MATERIAL

Concept and Distribution

Glaciolacustrine material is calcareous, fine-grained sediment deposited in glacial lakes and derived from calcareous unconsolidated and consolidated materials. Glaciolacustrine deposits occur mostly in the Montane and Lower Subalpine. Physiographic positions are mainly valley floors including benchlands. Known occurrences are in the lower Snake Indian and lower to middle Rocky River valleys in Jasper. In Banff, glaciolacustrine deposits occur in the lower and middle Mistaya, middle Pipestone and Cascade, and lower Spray River valleys and the Johnston Creek valley above Johnston Canyon. Noncalcareous glaciolacustrine material is of very limited extent. A noteable example occurs as a discontinuous veneer overlying noncalcareous ice contact stratified drift in the upper Miette River valley in Jasper.

Surface Expression and Modifying Processes

Glaciolacustrine material commonly occurs as blankets and veneers overlying ridged, hummocky, and undulating glacial landforms. These

are commonly complex slopes ranging from 0 to 10%.

Fluvial, fluviolacustrine and eolian processes commonly modify glaciolacustrine landform surfaces. Process status may be active or inactive. Fluvial and fluviolacustrine veneers are common on wet portions and eolian veneers are commom on dry portions. Ponding occurs occasionally on wet portions.

Textural Properties

Glaciolacustrine material commonly displays textures high in silt and clay content, hence the genetic material is labelled fine. Sand content commonly ranges from 0 to 10%, clay content from 30 to 50%. This range includes part of the silty clay loam and silty clay textural classes as defined by C.S.S.C. (1978a). Fig. 18 shows textural variation among selected C horizon samples of glaciolacustrine material. Coarse fragments are usually absent. Stratification, displaying layers with high silt content, occur locally.

Calcareousness and Reaction Properties

Glaciolacustrine material is usually calcareous, ranging from very strongly to extremely calcareous (C.S.S.C. 1978a) with pH values ranging from 7.2 to 7.4. Noncalcareous glaciolacustrine material is rare.

Discussion

Glaciolacustrine material is only recognized in the Montane and Lower Subalpine. It

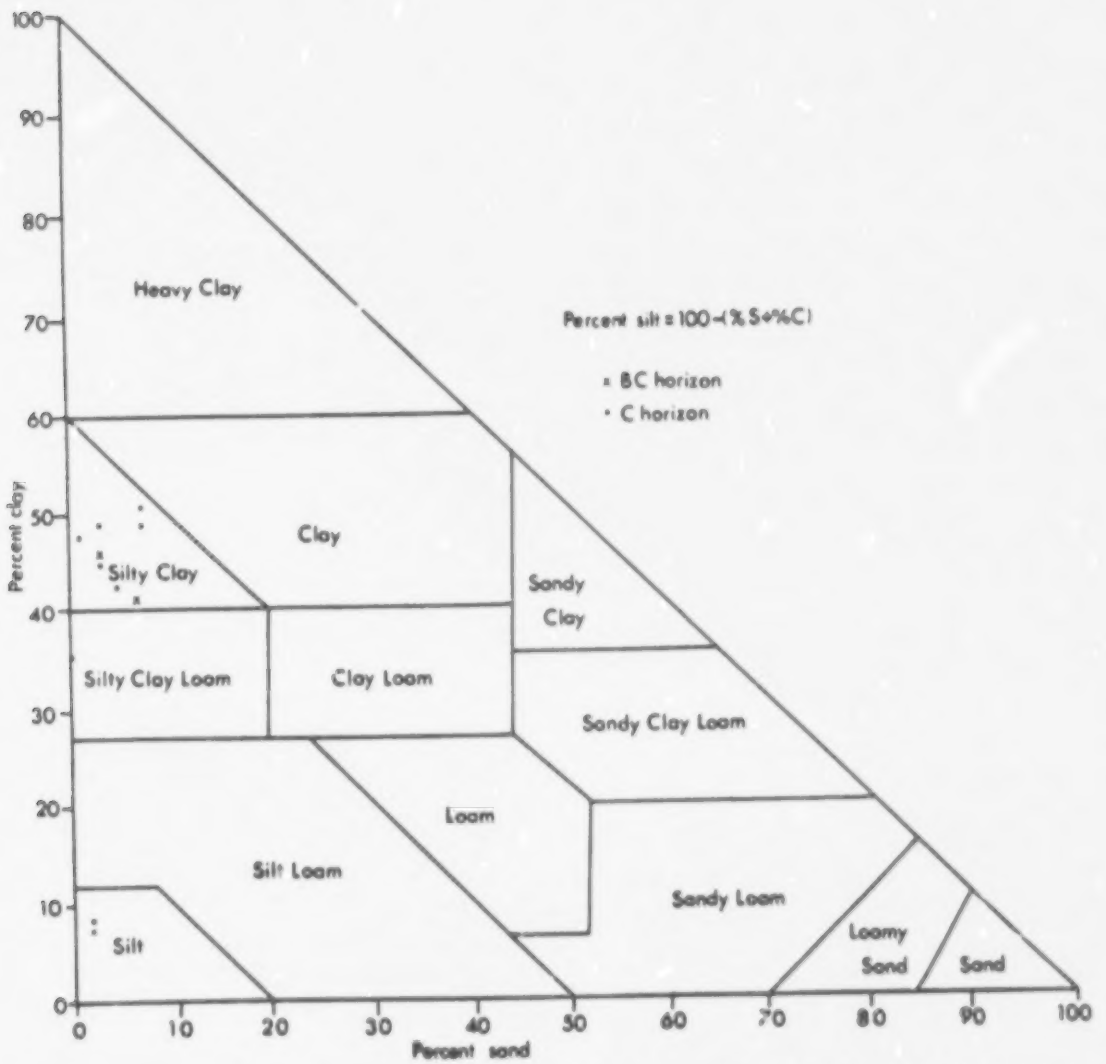

Figure 18 Textural variation among selected BC and C horizon samples of fine textured glaciolacustrine material.

dominates the glaciolacustrine landforms of the Nashan (NH) and Rocky (RK) Ecosections of the Montane, and the Merlin Castle (MC) and Spray (SP) Ecosections of the Lower Subalpine.

Thin veneers of altered, medium textured eolian material (Eolian material B) and altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) occasionally overlie Glaciolacustrine material. Glaciolacustrine material on dry portions is dominated by Luvisolic and Brunisolic soils. A range of wet soils that include Gleysols and gleyed Brunisols dominate the wet land.

EOLIAN GENETIC MATERIAL

Eolian sediment encompasses material deposited by wind. In Banff and Jasper, eolian deposits, also termed loess, are well sorted and dominated by silt (rarely <50%).

Eolian material is probably the most extensive unconsolidated mineral genetic material, but only in limited areas does it consistently exceed 30 cm in thickness. Eolian material thinly mantles many other genetic material landforms, but seldom alters their surface expression. Thicker, ridged eolian deposits (dunes) of mappable extent occur in the lower Athabasca River valley near Jasper Lake. Local eolian landforms also border extensive areas of bare mineral soil, such as near the confluence of the North Saskatchewan and Howse Rivers.

Two eolian material units are identified in Banff and Jasper, differentiated primarily on chemical (calcareousness) properties. Calcareous, medium textured eolian material (Eolian material A) is limited in distribution and encompasses thick, currently aggrading deposits, usually in the Montane Ecoregion. Altered medium textured eolian material (Eolian material B) forms thinner deposits on stable landscapes throughout Banff and Jasper. Its altered chemical properties reflect pedogenic weathering processes, showing it is older and/or more slowly aggrading than Eolian material A.

EOLIAN MATERIAL A

Concept and Distribution

Eolian material A encompasses calcareous, medium textured sediment deposited by wind. Occurrences are restricted to valley floors, benchlands, and lower valley wall slopes within the Montane Ecoregion. Deposits are mapped in the Athabasca River valley northeast of the Palisades in Jasper and in the Howse/North Saskatchewan River valley east of Glacier Lake in Banff. Distribution elsewhere is very limited, one example being the dunes occurring 1 km southeast of Banff airstrip (Rutter 1972).

Major source areas for Eolian material A include the wide, braided channels of the Athabasca River in Jasper and the Howse/North Saskatchewan Rivers in Banff. Winds channeled down these valleys pick up silt, fine and very fine sand, and some clay from the loose, unvegetated, glaciofluvial surfaces and transport them down valley (see Plate 101 in Chapter IV). Deposition occurs primarily in vegetated areas on valley floors, benchlands, and lower valley wall slopes. Process status for Eolian material A is active, based on associated soil development. Degree of activity (rate of deposition) decreases upslope from the valley floors.

Surface Expression and Modifying Processes

Eolian material A forms ridged landforms (dunes) on the Athabasca River floor from the head of Jasper Lake to Jasper's East Gate. These belong to the Devona (DV) Ecosection. Thickness of Eolian material A ranges to about 25 m in the Jasper Lake/Talbot Lake area but is shallower down valley. Slopes range from 5 to 30%.

Above the valley floor, Eolian material A forms veneers and, occasionally, blankets overlying the glacial deposits dominating the rivers' erosional scarps, benchlands, and lower valley wall slopes. Deposits are thickest (approximately 1 m) near the valley floors and become thinner upslope away from the river channels. Underlying deposits include morainal and ice contact stratified drift deposits. Inclined, hummocky, and ridged surface expressions reflect river erosion, bedrock control, or glacial deposition and are not masked by the eolian deposits. Slopes commonly range from 5 to 70%. Such polygenetic landforms typify the Talbot (TA) Ecosection. Veneers of Eolian material A mantle other landforms on valley floors along the lower Athabasca River in Jasper and the North Saskatchewan River in Banff (e.g. fluvial fans, glaciofluvial terraces).

Processes modifying Eolian material A are primarily those which erode, mix, and rework surface layers. Deflation producing blowouts is common on the dune landforms. Shallow tree root systems often occur on landforms with eolian veneers and the trees are susceptible to wind throw. This process often mixes underlying material with Eolian material A. The effects of water are intermittent and localized and include erosion and reworking of surfaces by sheet flow, stream channel overflow, and gullying on steep morainal slopes.

Textural Properties

Modally, Eolian material A is medium textured and typified by high silt content (rarely

<50%). Sand content commonly ranges from 0 to 40%; clay content from 5 to 20%. The sand fraction is typically dominated by the fine and very fine sand size separates. Coarse fragments are usually absent but may range to 5% by volume. These are generally introduced by mixing processes such as wind throw of trees.

Textural variation among selected A, B, and C horizon samples of Eolian material A is shown in Fig. 19. It is assumed that pedogenic alteration has had little effect on textural qualities of A and B horizons. A coarse textured variant, with up to 70% sand, dominated by the fine and very fine sand separates, occurs adjacent to source areas in Jasper. However, the sand content diminishes rapidly downwind from source areas.

Other physical features of Eolian material A include low bulk density (0.7-1.2 g/cm³ measured on 4 horizons), very friable consistence, massive structure, and lack of mineral stratification. Buried organo-mineral (Ahb) horizons may occur and mark the positions of nearly stable, slowly accreting surfaces that were subsequently buried by renewed, more rapid eolian deposition.

Calcareousness and Reaction Properties

Eolian material A is usually strongly to extremely calcareous and mildly to moderately alkaline. Calcium carbonate equivalent contents commonly range from 15 to 70%; pH values from 7.3 to 8.3.

Weakly developed pedogenic horizons occur at

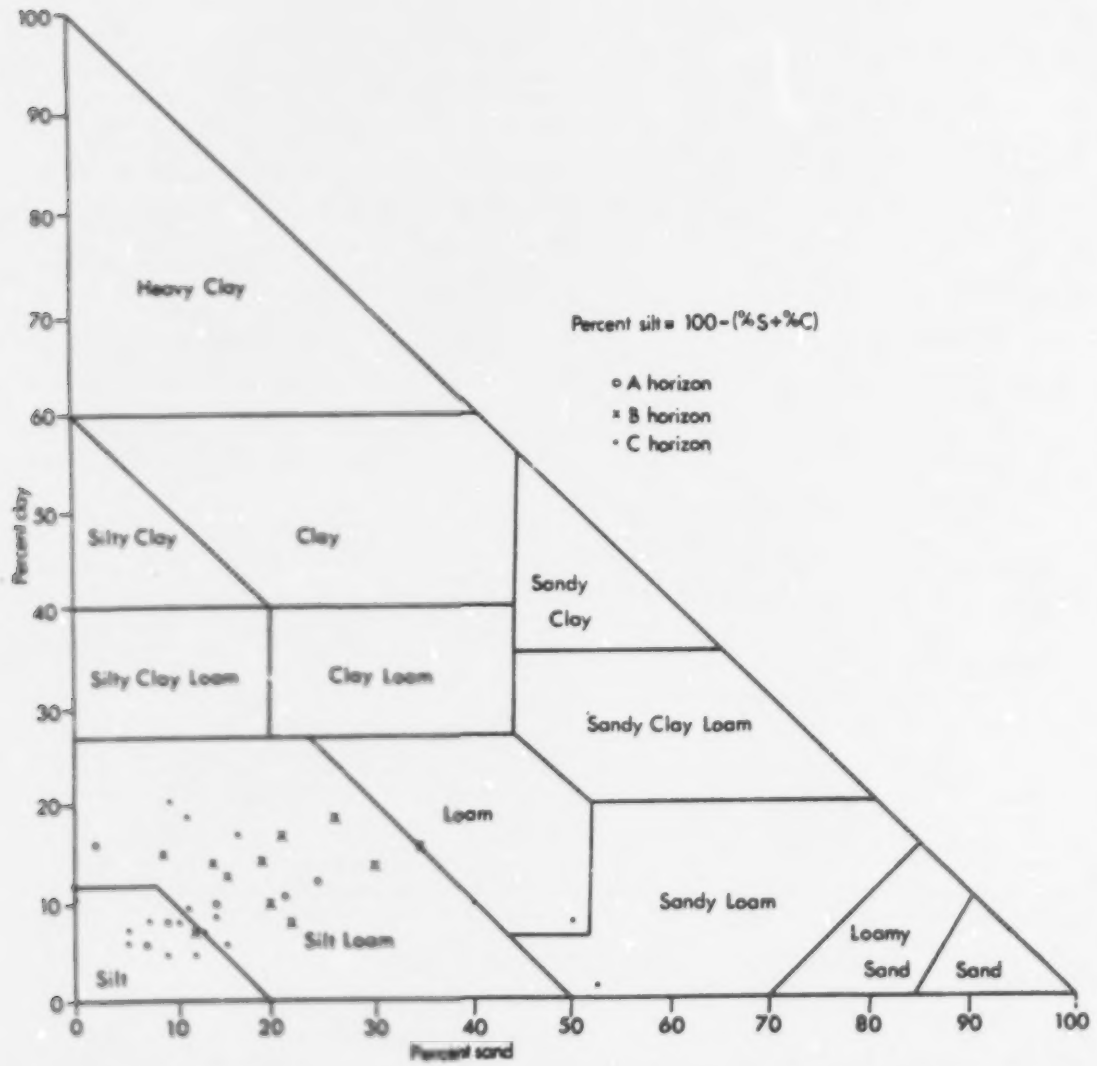

Figure 19 Textural variation among selected A, B, and C horizon samples of calcareous, medium textured eolian material (Eolian material A).

higher elevations where deposition rates are low. These plus buried A and B horzons may have lower carbonate content (rarely <1%) and pH (rarely <7.0), although they commonly contain secondary carbonate illuviated from layers above. Hence, Eolian material A surfaces are continually receiving varying amounts of calcareous material.

Discussion

Calcareous, medium textured eolian material (Eolian material A) is the thickest but least extensive of the two eolian material units. It is restricted to the Montane Ecoregion and occurs in the lower Athabasca River valley in Jasper, and the Howse/North Saskatchewan River valley in Banff. The ridged landforms of the Devona (DV) Ecosection are comprised of Eolian material A. Landforms of the Talbot (TA) Ecosection are characterized by Eolian material A veneers overlying glacial deposits.

A minor constituent of Eolian material A is volcanic ash. Westgate and Dreimanis (1967) described two distinct volcanic ash layers plus reworked ash layers in a section through a loess deposit near Saskatchewan Crossing in Banff. Grain size distribution of Bridge River ash samples presented by Westgate and Dreimanis (1967) is similar to that of Eolian material A.

EOLIAN MATERIAL B

Concept and Distribution

Eolian material B encompasses chemically altered, medium textured sediment deposited by wind. It is the most extensive of the unconsolidated mineral materials, but rarely exceeds 30 cm in thickness. It mantles a variety of landforms on all physiographic positions in all Ecoregions but is most extensive on older, relatively stable surfaces such as morainal landscape. Depth and extent of Eolian material B veneers are greatest in the southwest and decrease to the north and east. Hence, the deepest (15 to 30 cm) and most extensive deposits occur on stable surfaces in western Banff (including southern Banff south of the townsite) and southwestern Jasper.

Smith (1979) presents evidence that veneers of eolian origin (Eolian material B) occurring as the upper sola of pedons in the Sunwapta Pass area of Jasper are composed of local detritis with admixed volcanic ash. Other soil studies conducted in the North Saskatchewan River valley outside Banff National Park (Pettapiece and Pawluk 1972), in the Sunshine area (Pawluk and Brewer 1975) and at Bow Pass (King and Brewster 1976) provide substantiating evidence. Surface (upper sola) occurrences of eolian sediment containing volcanic ash are documented for Banff and southern Jasper and areas immediately east of the parks (Westgate and Dreimanis 1967, Pettapiece 1971, Beke and Pawluk 1973, Knapik et al. 1973, Pawluk and Brewer 1975, King and Brewster 1976, and Smith 1979). Ash layers buried by colluvial, fluvial, fluviolacustrine, eolian, and organic deposits have also been recorded within and adjacent to Banff and Jasper (Westgate and Dreimanis 1967, McPherson and Hirst 1972, Smith 1972, Roed and Wasylyk 1973, Smith 1975). Several of these researchers have identified three major postglacial ashfalls, traceable to major volcanic events occurring in the northwestern United States and southwestern British Columbia. Ejecta plumes tracked northeastwards from the sites of volcanism (Powers and Wilcox 1964, Nasmith et al. 1967, Westgate and Dreimanis 1967, Harward and Youngberg 1969, Westgate et al. 1969). The three major ashfalls are Mazama ash dated to 6600 years B.P., St. Helens Y ash dated to approximately 3200 years B.P., and Bridge River ash dated to about 2400 years B.P. The most extensive ash is Mazama.

Surface veneers containing ash do not have discrete strata comprised of ash and/or local detritis. Hence, Eolian material B is essentially mineralogically uniform (Smith 1979), its constituents having been mixed by various agents including redeposition by wind, windthrow of trees, soil creep, and solifluction. Fresh moraine, outwash plains, and exposed, unvegetated colluvium and rock are the local sources winnowed to produce detritus for eolian transport and deposition. It is thought that over most of Banff and Jasper, accumulation of Eolian material B has essentially ceased, with only microscopic amounts presently accreting. Areas adjacent to glaciers, fresh moraines and unvegetated glacial meltwater channels may receive more wind-blown material.

Surface Form and Modifying Processes

Eolian material B occurs most extensively as thin (usually <30 cm) veneers mantling relatively stable surfaces of older genetic materials and bedrock. The most common underlying material is glacial till. The veneers are discontinuous, having been subjected to redeposition by wind and post-depositional, erosional and mixing processes. These processes include sheet erosion (washing), gully erosion, colluviation, avalanching, and, at high elevations, solifluction and cryoturbation. On wet, seepage-affected landscape, washed and redeposited Eolian material B is a common constituent of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A).

Textural Properties

Modally, Eolian material B is medium textured and typified by high silt content (rarely <50%). Sand content commonly ranges from 10 to 50%; clay content from 0 to 25%.

The sand fraction is dominated by the fine and very fine sand size separates. Coarse fragments are usually absent but may range to 5% by volume. These are generally introduced from underlying materials by pedoturbation processes such as windthrow of trees, soil creep, and solifluction.

Textural variation among selected A, B, and C horizon samples of Eolian material B is shown in Fig. 20. It is not known to what extent pedogenic weathering and eluviation have altered the textural qualities of A and B horizons. Altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) consisting of reworked and redeposited Eolian material B usually displays higher clay content than its precursor. Other physical features of Eolian material B include low bulk density (0.6-1.4 g/cm^3 measured on a few samples), very friable consistence, massive structure, and a lack of mineral stratification. Bulk density, consistence, and structure are similar for Fluviolacustrine material A and calcareous, medium textured eolian material (Eolian material A).

Calcareousness and Reaction Properties

Chemical properties of Eolian material B are termed altered. This is because it occurs as surficial veneers, thereby comprising the mineral surface of soils where pedogenic weathering is the strongest. With sufficiently long periods of stability, leaching of carbonate and acidification occur during A and B horizon

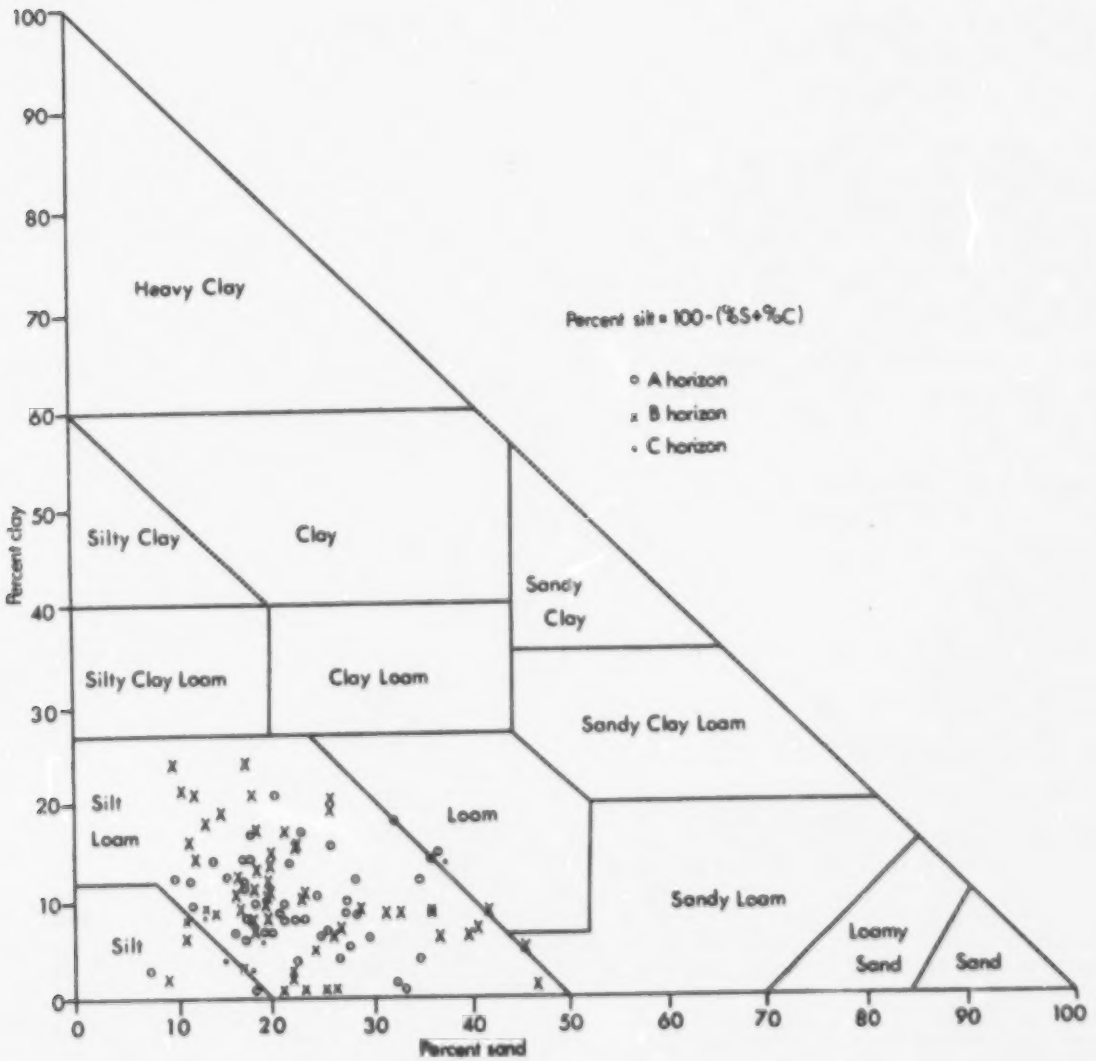

Figure 20 Textural variation among selected A, B, and C horizon samples of altered, medium textured eolian material (Eolian material B).

development. Consequently, the original calcareousness and reaction qualities are unknown.

Soils occurring in Eolian material B veneers overlying other genetic materials are frequently characterized by somewhat amorphous, very friable B horizons with moderate to high chroma developed above the parent material disconformity. This distinctive B horizon often contains high amounts of pyrophosphate-extractable (organically complexed) iron and aluminum and, at high elevations, high humus contents. Free iron and aluminum oxide are derived by weathering of primary minerals from both ash and non-ash (local) sources (Smith 1979).

Discussion

Altered, medium textured eolian material (Eolian material B) is the thinnest but most extensive of the two eolian material units. No Ecosection or Ecosite separations in the Banff-Jasper Ecological Land Classifictaion system are based on the presence of this material. It is, however, a common but inconspicuous component of many Ecosites. Ecosites characterized, in part, by Podzolic soils or Brunisolic Gray Luvisols have, as an accessory feature, eolian veneers referring specifically to Eolian material B. Gleyed Podzolic soils occur on wet, seepage-affected landscape, their upper sola horizons being developed mainly in Fluviolacustrine material A consisting primarily of reworked Eolian material B. Volcanic ash occurring as thin buried layers within organic and stratified fluvial deposits is included within the concept of Eolian material B.

ORGANIC, CONSOLIDATED, AND ICE COMPONENTS

The organic, consolidated, and ice components are not subdivided within the Banff-Jasper Ecological Land Classification taxonomy. The organic component is of limited areal extent and thinly mantles unconsolidated mineral deposits. The consolidated (bedrock) and ice components lack soil and vegetation.

ORGANIC COMPONENT

The organic component consists of peat deposits containing >30% organic matter by weight (>17% organic carbon) that may be as thin as 10 cm if they overlie bedrock but are otherwise greater than 40 cm (C.S.S.C. 1978b). In Banff and Jasper the organic component is of limited areal extent and thinly mantles unconsolidated mineral deposits.

Organic landforms consist predominantly of fen peat, represented by the component symbol N, derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). In several areas fen vegetation has been succeeded by open and closed forest.

Ground water discharge and high water tables promote the development of organic material. Fens develop where the mineral component is stable, thus enabling build up of organic material. These locales are very poorly to poorly drained and are frequently ponded. Favorable moisture, nutrients and vegetation have resulted in the accumulation of varying thicknesses of fen peat but they rarely exceed 1.2 m in thickness.

Fen peat is medium acid to neutral (pH 5.5-7.5) in reaction. Moderate decomposition is characteristic but fibric and humic layers also occur. Fen peat is relatively low in fiber with a 10 to 40% rubbed fibre content (C.S.S.C. 1978b). Organic materials occasionally contain partially decayed wood fragments. They may also contain thin layers of altered, medium textured eolian material (Eolian material B).

Topographically, organic landforms display gentle linear slopes commonly ranging from 0 to 15%. Two classes exist in the parks, horizontal and sloping. These occupy level floodplains and toes of fluvial aprons and fans. They also occur on sloping discharge and depressional areas on glacial and proglacial landforms.

Organic landforms occur in all Ecoregions of Banff and Jasper but are most extensive in the Montane and Subalpine. In the Montane Ecoregion organic landforms comprise part of the Patricia 5 (PT5) and Vermilion Lakes 1 (VL1) Ecosites. They comprise minor portions of the Nashan 1 (NH1) and Vermilion Lakes 3 (VL3) Ecosites. In the Lower Subalpine, organic landforms comprise part of Baker Creek (BK) and Consolation Valley (CV) Ecosections and part of the Cavell 1 (CA1), Topaz (TZ2) and Hector 1 and 4 (HC1, HC4) Ecosites. They comprise minor portions of the Merlin Castle 1 (MC1) Ecosite. In the Upper Subalpine, organic landforms comprise parts of the Azure 1 (AZ1) and Num-Ti-Jah 3 (NT3) Ecosites. In the Alpine Ecoregion, organic landforms are of minor importance. Organic layers occur locally in several other Ecosites throughout all Ecoregions of the parks.

CONSOLIDATED COMPONENT (BEDROCK)

Bedrock is the only consolidated component class recognized. It consists of tightly packed lithified materials. Excluding materials indurated by pedogenic processes, bedrock is material harder than 3 on Mohs' hardness scale. Effectively, this is material too hard to break with the hands or to dig with a spade when moist (C.S.S.C. 1978b).

Bedrock underlies all other materials in the

parks, at greatest depths in the major valley floors. It crops out throughout all Ecoregions, with locations dependent on lithology, structure, and erosional history. Most outcrop occurs at high elevations. Surface expressions are generally steep, but at lower elevations there are ridged and occasionally hummocky instances. Massive, resistant rock is more prominent in the landscape than recessive bedrock.

Bedrock is the source of all unconsolidated mineral material in the parks save the volcanic component of Eolian material B. For purposes of this Ecological Land Classification, three major lithologic groups are important (Table 5). Though these groups strongly influence their immediate landscape, especially in areas where unsorted sediments are derived directly from them, bedrock as such is not subdivided.

The Miscellaneous Landscape Rockland (R) is mapped with bedrock as the principal landform, as is the Heather 2 (HE2) Ecosite.

ICE COMPONENT

The ice component forms by the compaction and recrystallization of year-round snow. In Banff and Jasper this includes glaciers, icefields, glacierettes, and firn. The ice component occurs mainly in the Upper Subalpine and Alpine. Occurrences are rare in the Lower Subalpine, and restricted to ablating valley glaciers fed from higher elevations. Distribution of ice is primarily confined to higher elevations of the Main Ranges near the Continental Divide (Falconer et al. 1966). Occurrences and extent are limited in the Front Ranges. The ice component lacks soil and vegetation except for snow mold. In some cases though, ice is often mantled by colluvial and landslide debris from adjacent steep slopes. The ice component within Banff and Jasper is identified as the Miscellaneous Landscape Glacier (GL).

CHAPTER II

SOILS

B.D. Walker, W.D. Holland,
and G.M. Coen

INTRODUCTION

Early systematic soil description and classification in Alberta started on agricultural land in the 1920's. Soils work on the periphery of Banff and Jasper includes soil description and classification in the Subalpine forest at the Kananaskis Forest Experiment Station (Crossley 1951), Laycock's (1957) physiographic classification of soils for land use planning of the Eastern Slopes of the Canadian Rockies, and a soil survey of Marmot Creek basin (Lindsay and Peters 1964). Land classification using biophysical principles was conducted by Pettapiece (1971) along the North Saskatchewan River valley. Other work east of the parks included land classification at Kananaskis by Duffy and England (1967) and studies by Dumanski (1970), Dumanski and Pawluk (1971), and Dumanski et al. (1972) investigating the genesis of soils developed on calcareous eolian material in Jasper and near Hinton, along with soil survey and land evaluation in the Hinton-Edson area. Soil survey and interpretations in the mountains and foothills of the Wapiti map area north of Jasper Park were conducted by Twardy and Corns (1980).

Soil survey to the west of Banff was done by Kelley and Sprout (1956), Kelley and Holland (1961) and in Yoho by Coen et al. (1977).

Description and classification of soils in Banff and Jasper were begun fairly recently. Initial efforts were site specific and linear transect studies, mostly as student research, but gradually became oriented to answering particular park problems. Among these workers were Baptie (1967) on the ecology of Alpine soils, King (1971) investigating soil in Castleguard Meadows, and Knapik (1972) and Knapik et al. (1973) looking at soils and soil and plant relationships in the Sunsine ski area. Ogilvie and Baptie (1967) reported on permafrost, as did Scotter (1975) and Achuff and Coen (1980). Root and Knapik (1972), followed by Epp (1977), examined soils in relation to trail conditions.

A number of site specific studies provided descriptions of soils and vegetation, for example the visitor impact study in the Sunshine-Egypt Lake area of Banff where Lesko and Robson (1975) examined damage to vegetation and soils as a result of campground use. Site specific descriptions in Banff and Jasper were prepared by Knapik and Coen (1978) for a tour by members of the International Society of Soil Science.

Soil survey and land inventory studies were begun in Banff by Noakes and Harris (1971), Harris et al. (1973), Harris (1974), and the Lombard North Group Ltd. (1974). The early land classification projects were superseded by the work of Walker et al. (1978), using the biophysical land classification methods and concepts of Lacate (1969) and Holland (1976). Broad scale holostic land classification for southwestern Alberta was reported by Kojima (1980) using the biogeoclimatic methodology of Krajina (1959), and information supplied by the Banff-Jasper Ecological Land Classification team.

A wide range of techniques and presentations of natural resource inventories is evident from the foregoing, the nature of which is dependent upon the purpose and recipient of the information. A common theme is the development of techniques and concern for improved description, inventory, classification, and interpretation of the soil resource in relation to other resources. Ultimately, it is hoped that such study will develop an appreciation for improved park land use and conservation of soil and other resources.

SOIL FORMATION, TAXONOMY, AND DISTRIBUTION

FACTORS OF SOIL FORMATION

Five environmental factors are generally considered to affect soil formation, and are discussed in detail by Jenny (1941), Buckman and Brady (1969), and Buol et al. (1973). These factors are climate, particularly temperature and precipitation; living organisms, especially the type of vegetation cover and organic matter accumulation; tne kind of parent material, that is, its texture, mineralogical and chemical composition; the relief of the area, including topography, elevation and drainage; and finally the time (or length of stability) that parent materials are subjected to soil formation.

The interaction of these soil-forming factors has resulted in many different kinds of soil throughout Banff and Jasper. The relative importance of each factor differs from place to place. Site specific pedogenic studies in Banff, Jasper, and adjoining areas are of interest from the standpoint of gaining some insight into ecological relationships. Several pedogenic studies deal with soil pedons developed from two different geomorphic materials, the upper one being of eolian origin and containing varying amounts of volcanic ash and the lower one being mainly of morainal origin. These studies were conducted on soils from the North Saskatchewan River valley east of the Banff National Park boundary (Pettapiece and Pawluk 1972), Marmot Creek basin southeast of Banff (Beke and Pawluk 1971), the Sunshine area in Banff and Luscar Mtn. east of Jasper (Pawluk and Brewer 1975), Bow Pass in Banff (King and Brewster 1976), and Sunwapta Pass in Jasper (Smith 1979). Pettapiece and Pawluk (1972) and Smith (1979) investigated "besequa" profiles with podzolic-like morphologies overlying luvisolic-like morphologies. Pawluk and Brewer (1975) point out the importance of soil fauna in the development of Alpine soils. Dumanski and Pawluk (1971) investigated soils developed in calcareous, eolian deposits located between Jasper's East Gate and Hinton. Baptie (1967) studied the ecology of soils in the Snow Creek valley, Banff. Achuff and Coen (1980) noted climate—soil—vegetation relationships for a Cryosolic soil in the Mt. White area in eastern Banff.

SOIL ORDERS IN BANFF AND JASPER

The soil taxonomy used in Banff and Jasper is the Canadian System of Soil Classification (C.S.S.C. 1978b). Representatives of eight soil Orders occur in the parks, including the Brunisolic, Luvisolic, Podzolic, Chernozemic, Cryosolic, Regosolic, Gleysolic, and Organic Orders.

The first three reflect, by their degree of horizon differentiation and certain morphological characteristics, various mesoclimates within the broader Ecoregions and certain parent material characteristics. The Chernozemic and Cryosolic Orders appear to be controlled by meso- or microclimatic influences and rather specific but unidentified parent material characteristics which affect small geographic areas. The Regosolic Order reflects active or recently active geomorphic processes. The Gleysolic and Organic Orders reflect the interaction of topography and hydrologic flow regimes (high water tables, near-surface seepage, groundwater discharge, and surface water collection).

Soils of the Brunisolic Order are the most abundant of those Orders occurring in Banff and Jasper. Changes in the balance of soil forming factors tends to result in changes in soil characteristics along a taxonomic continua toward other Orders. Many of the Ecosites are characterized by soils occurring along this continua near the Brunisolic Order boundary with other Orders.

THE BRUNISOLIC ORDER

In Banff and Jasper, the Brunisolic Order is broad in concept, the most extensive relative to other Orders, and encompasses a wide range of characteristics. Brunisols are frequently associated with soils of several other Orders under varying climatic, vegetational, and geomorphic conditions. These characteristics and relationships are explored briefly in the discussion that follows.

Great Groups

The Brunisolic Order is subdivided into 4 Great Groups based on solum reaction and A horizon characteristics. All four Great Groups occur in Banff and Jasper.

A major distinction is based on solum reaction. Eutric and Melanic Brunisols have medium acid to mildly alkaline (pH >5.5), middle to lower sola, including specifically the B horizon and underlying horizons to a thickness of 25 cm. They are developed on calcareous geomorphic materials including, in some areas, those with low lime content.

Dystric and Sombric Brunisols are common in Banff and Jasper, but less extensive than the Eutric and Melanic Brunisols. Dystric and Sombric Brunisols have extremely to strongly acid (pH of 5.5 or less), middle to lower sola, including specifically the B horizon and underlying horizons to a thickness of 25 cm. They are developed on noncalcareous geomorphic materials including, in some areas, those with low lime content.

Melanic and Sombric Brunisols are distinguished from Eutric and Dystric Brunisols, respectively, by thick (10 cm or more)

organo-mineral (Ah) horizons. Such horizons develop under non-forested vegetation where organic matter incorporation and humification is important. Soil fauna are important in these processes (Pawluk and Brewer 1975). These two Great Groups occur in complex environments where Ah horizon thickness is quite variable and other processes are important locally. Hence, Melanic and Sombric Brunisols are intimately associated with Eutric and Dystric Brunisols and soils of several other Orders. A horizon features of Brunisolic soils are explored in greater detail in a following section.

B Horizon And Lower Solum Characteristics of Brunisolic Soils

As previously mentioned, Brunisolic soils display a wide range of characteristics. This is particularly pertinent to Brunisolic B horizon and lower solum development. B horzon differentiation ranges from weak (Brunisolic—Regosolic soil complexes) through intermediate to strong (Brunisolic—Podzolic soil complexes) including those with luvisolic tendencies (Brunisolic—Luvisolic soil complexes), depending on mesoclimatic and geomorphic conditions. Lower sola may also display evidence of weak gleying, related to drainage characteristics.

Brunisolic soils with weakly expressed and poorly differentiated B horizons (5 cm or more thick) are often associated with Regosolic soils on some geomorphically active terrain. Orthic Dystric Brunisols, Orthic Eutric Brunisols, and Orthic Melanic Brunisols are the Subgroups most often found in such situations. Steep colluvial landforms frequently have a Brunisol—Regosol soil complex but some landslide deposits, steeply sloping morainal tracts, and recently stabilized fluvial landforms display a similar soil pattern. The geomorphic processes generally involve differential (locally varying intensity) erosion or deposition and include avalanching, soil creep, sheet and gully erosion, windthrow of trees, fluvial deposition, eolian deflation and deposition, solifluction, and cryoturbation. Recently stabilized slopes also frequently exhibit a Brunisol—Regosol soil pattern.

Eutric Brunisols occurring on warm, dry glacial and glaciolacustrine landforms in the Montane and Lower Subalpine frequently have B horizons with luvisol-like morphologies. These Orthic and Eluviated Eutric Brunisols are intimately associated with Luvisolic soils and have brownish (often 7.5YR 4/4 m; Munsell color notation) Bm or Btj horizons developed at the mineral surface or below an Ae—Bm horizon sequence occurring in thin veneers of altered, medium textured eolian material (Eolian material B), where present. These B horizons display high clay contents compared to adjacent horizons, but structure (subangular blocky) and clay film development are weak. They also frequently show evidence of incomplete carbonate removal. The Brunisol—Luvisol complex of soils are generally well to moderately well drained, occasionally rapidly and imperfectly drained, and occur under lodgepole pine forests. Mesic to subxeric Engelmann spruce—subalpine fir forests, namely the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower /feathermoss (C31) and Engelmann spruce/hairy wild rye (C33) v.t.s ocurring on southerly aspects in the Front Ranges, are also associated with Brunisolic soils displaying luvisolic tendencies. In some areas, this soil complex extends as high as 2000 m on southerly aspects and 1800 m on northerly aspects but the luvisolic tendencies diminish and the incidence of Luvisolic soils decreases with increasing elevation.

Brunisolic soils with moderate or intermediate horizon development occur under intermediate mesoclimatic conditions or on stable genetic materials that do not promote luvisolic or podzolic tendencies as a result of pedogenic weathering. These materials include glacial landforms on northerly aspects and at high elevations in eastern Banff and eastern and northern Jasper, fluvial and glaciofluvial landforms with old, stable surfaces, some Subalpine landslide and residual landforms, and, occasionally, noncalcareous colluvial landforms. The moderately developed Brunisols generally have brownish Bm horizons with low to moderate amounts of humus and pyrophosphate extractable iron and aluminum. Underlying horizons (BC or lower B horizons) occasionally exhibit rudimentary luvisolic tendencies, especially where developed on calcareous glacial materials, but such features are attributed primarily to differential removal (weathering) of carbonate material from the soil mass (Smith 1979). Eluviated Dystric Brunisols with duric tendencies (weak cementing) in lower B and BC horizons occur frequently on noncalcareous, coarse textured materials, namely noncalcareous, coarse textured till (Till A), noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A), and noncalcareous, coarse textured glaciofluvial material (Glaciofluvial material A). These soils also dislay unusually deep Ae horizons and sola where Eolian material B is absent. The moderately developed Brunisols occur under rapidly to imperfectly drained moisture conditions and a variety of vegetation types, excluding most lodgepole pine forests occurring on calcareous glacial materials.

Under cool, moist Subalpine and Alpine climatic conditions where veneers of Eolian material B are extensive, Brunisolic soils are generally strongly developed, displaying podzolic tendencies, and associated with Podzolic soils. Distribution of these soils corresponds to the distribution of Eolian material B under well to moderately well drained conditions

and altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) derived from Eolian material B under imperfectly to poorly drained conditions. Hence, the Brunisol—Podzol complex of soils is most extensive in western Banff and southwestern Jasper, particularly on glacial landforms. These soils occur under Engelmann spruce—subalpine fir forests at intermediate elevations, under subalpine larch and heath tundra vegetation at higher elevations. The strongly developed Brunisols are characterized by reddish, dark and strong brown Bm, Bfj, Bf, or Bhf horizons developed immediately above the parent material disconformity. These horizons have moderate to high pyrophosphate extractable iron and aluminum contents, weathered from the eolian genetic material. They also display, generally, increasing illuvial—humus content with elevation or with increasing wetness (imperfectly to poorly drained). Under forest vegetation, eluvial (Ae) horizons often overly the B horizons. In the Alpine and Upper Subalpine—Alpine ecotone, overlying horizons are humus rich (Ahe or Ah). Underlying genetic materials may be either calcareous, giving Eutric and Melanic Brunisols, or noncalcareous, resulting in Dystric and Sombric Brunisols.

Brunisolic soils exhibiting the full range of B horizon characteristics occur under imperfectly to poorly drained conditions on sites affected by seepage. These are usually intimately associated with Gleysolic and gleyed Podzolic soils. The most common Subgroups are Gleyed Dystric Brunisols and Gleyed Eutric Brunisols. They generally display weak mottling in a matrix background of moderate chroma. Consequently, evidence of strong gleying and anaerobic conditions, i.e. dull colors and/or strong mottling, is absent from the upper 50 cm of mineral soil, even though neighboring pedons may be strongly gleyed. A variety of climatic, geomorphic, and hydrologic factors contribute to the varying intensity of gleization across seepage affected landscape. Thin organic layers (peaty horizons) may or may not mantle the mineral soil. A horizons are absent or thin and where present, are generally Ah or Ahe. Eluvial (Ae) horizons occur infrequently. Gleyed Brunisolic soils are common on glaciolacustrine landforms in the Lower Subalpine but are most extensive on seepage affected morainal landforms in the Upper Subalpine.

A Horizon Characteristics of Brunisolic Soils

Brunisolic soils occasionally lack A horizons. Frequently this is because current or recent disturbances have destroyed them or inhibited their development. On more stable slopes, eluvial (Ae) horizons are common under forest vegetation. Ae horizons >2 cm thick, are diagnostic for Eluviated Subgroups within the Brunisolic Order. Of particular interest are the organo-mineral (Ah) horizons associated with Brunisolic and other soils occurring in the Alpine and Alpine—Upper Subalpine ecotone and under grassland and dry shrubland vegetation. In both environments, the Ah horizon thickness is variable and largely controlled by the kind and degree of surface disturbance. Some disturbances such as solifluction and soil creep disrupt A horizon development on some sites and physically thicken them on adjacent sites. The variable Ah horizon thickness results in the intimate association of Eutric with Melanic Brunisols, Dystric with Sombric Brunisols. Soils of other Orders, but with similar surfaces, are associated with these Brunisolic soils. However, the two environments display some basic differences.

Upper sola, including A horizons, of Brunisolic soils occurring under tundra vegetation tend to be acidic with low base saturation, regardless of the chemical characteristics of lower sola and C horizons. Further, the eluviation process is usually masked in the Alpine and Upper Subalpine—Alpine ecotone. However, under heath tundra vegetation, graying A horizons with characteristics of Ah and Ae horizons (herein termed Ahe horizons) often replace or coexist with Ah horizons. The presence of these Ahe horizons makes the distinction between Orthic and Eluviated Subgroups indefinite and each pedon must be evaluated as to degree of eluviation. Eluviated (Ae) horizons occur beneath thin Ah horizons in some pedons, particularly those developed on coarse textured materials under heath tundra vegetation. It is evident from this discussion that soil variability in the Alpine and Alpine—Upper Subalpine ecotone is great. Several Brunisolic Subgroups are intimately associated, as are soils from the Podzolic, Regosolic, and Gleysolic Orders.

Soils associated with Subalpine grasslands and dry shrublands are less variable than those in the Alpine and the Alpine—Upper Subalpine ecotone. Upper sola, incuding Ah horizons, of Brunisolic soils occurring in this warm, dry environment tend to have a neutral reaction with a high base saturation. They display a narrow range of pH from A to C horizons. Consequently, Ahe and Ae horizons giving Eluviated Subgroups are absent and, also, Dystric and Sombric Brunisols and Podzols do not occur. Recent or current geomorphic activity, mainly soil creep, is common on these steep, southerly-facing slopes (usually >30%) and Regosolic soils are common associates. There is evidence that some of the soils occurring under grassland vegetation can also be classed as Dark Brown in the Chernozemic Order. Some pedons have unusually thick Ah horizons resulting from the accretion of humified Ah material. Subalpine grasslands and dry shrublands are most common in but not confined to the Front Ranges. Shaly material, particularly that derived from Mesozoic strata, is a common con-

stituent of the morainal and colluvial materials supporting grassland and dry shrubland vegetation.

THE LUVISOLIC ORDER

Gray Luvisols occur in association with Eutric Brunisols showing luvisolic tendencies in warm, dry portions of Lower Subalpine and throughout much of the Montane. They commonly occur on calcareous, morainal, ice contact stratified, and glaciolacustrine landforms with rapidly to moderately well drained moisture regimes. Luvisolic development is best expressed on calcareous glaciolacustrine sediment.

Gray Luvisols are identified by eluvial Ae and illuvial Bt horizons, signifying presence of downwardly translocated clay. The subangular blocky structure is weak and clay films are thin and discontinuous, resulting in Bt horizons in Banff and Jasper being more weakly expressed than in much of the forested areas in Alberta. Additionally, these brownish (often 7.5YR 4/4 m, Munsell color notation) Bt horizons frequently display low carbonate content along their lower boundaries, indicating incomplete carbonate removal.

Very thin veneers of altered medium textured eolian material (Eolian material B) are common to areas with Luvisolic soils. The eolian material appears to be more easily weathered than the underlying glacial or glaciolacustrine material which it mantles. The result is an Ae—Bm horizon sequence like that of Brunisolic soils overlying the Bt horizon. Soils with such "bisequa" morphologies are classed as Brunisolic Gray Luvisol. Orthic Gray Luvisols occur where the veneer is absent, but their distribution is limited.

Gleyed Brunisolic Gray Luvisols occur occasionally and are most common on seepage affected (imperfectly drained) low lime till in the Lower Subalpine. The moraines exhibit evidence of slope failure but the seepage is periodic and affects only subsurface layers. Weak mottling in middle to lower sola and C horizons distinguishes the gleyed pedons from their better drained counterparts.

Lodgepole pine forests are usually associated with Luvisolic soils and their Eutric Brunisol associates. In a few areas, this soil—vegetation combination extends upwards as high as 2000 m on steep southerly aspects and 1800 m on northerly aspects. However, the luvisolic tendencies diminish and the incidence of Luvisolic soils decreases with increasing elevation. On some southerly aspects, spruce-fir forests, mainly the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) and Engelmann spruce/hairy wild rye (C33) v.t.s, are associated with the Brunisol—Luvisol complex of soils.

THE PODZOLIC ORDER

Podzolic soils represent the most strongly developed soils in Banff and Jasper. They are associated with Brunisolic soils displaying podzolic tendencies and are generally confined to moist, cool environments in the Subalpine and Alpine Ecoregions. Distribution is related to the distribution of altered, medium textured eolian material (Eolian material B) and its reworked derivative that forms a significant constituent of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) in some areas. Eolian material B and Fluviolacustrine material A veneers are thickest (generally up to 30 cm) and most extensive in western Banff and southwestern Jasper. The Brunisol—Podzol complex of soils are most extensive in this area.

Reddish to dark brown podzolic B horizons (C.S.S.C. 1978b) are diagnostic of Podzolic soils. These develop immediately above the parent material disconformity and contain high amounts (>0.6%) of pyrophosphate-extractable iron and aluminum weathered from the iron and aluminum containing minerals within the surficial veneers. There appears to be little translocation of iron and aluminum oxides across the parent material disconformity to underlying horizons (Beke and Pawluk 1971, King and Brewster 1976, Smith 1979).

Orthic Humo-Ferric Podzols are most common at moderate elevations under well to moderately well drained conditions with Engelmann spruce—subalpine fir and subalpine larch forests. These have podzolic Bf horizons. There is, however, a tendency towards increasing illuvial—humus content with elevation in the podzolic B horizons. Consequently, occurences of Orthic Ferro-Humic Podzols with podzolic Bhf horizons increase with elevation under well to moderately well drained conditions. These soils are more common than the Orthic Humo-Ferric Podzols under heath tundra vegetation in the Alpine and Alpine—Upper Subalpine ecotone. Under these conditions, the Orthic Ferro-Humic Podzols often have thin Ah horizons but occurrences of Sombric Ferro-Humic Podzols are infrequent.

Podzolic soils also occur under imperfectly to poorly drained moisture regimes in the Subalpine and Alpine Ecoregions. They are associated with Gleysolic, gleyed Brunisolic, and Organic soils on seepage affected terrain. Lower sola horizons display varying degrees of gleying. A and B horizons occur in thin veneers of Fluviolacustrine material A derived as a result of slope wash reworking and redepositing Eolian material B. Under these conditions, podzolic B horizons contain high amounts of humus as well as free iron and aluminum. They are classed as podzolic Bf, Bhf, and Bh, depending upon ratios of organ-

ic carbon to free iron and ratios of free iron plus aluminum to clay (C.S.S.C. 1978b). The generally high clay content of Fluviolacustrine material A plays an important role in classification of these horizons and soils. In imperfectly and poorly drained moisture regimes podzolic Bhf horizons, and the resultant Gleyed Ferro-Humic Podzols, are thought to be most abundant. Gleyed Humo-Ferric Podzols and Orthic Humic Podzols also occur under these conditions. Thin peaty surface horizons may or may not be present directly over the B horizon of over thin Ah or Ahe horizons.

Podzolic soils are associated primarily with morainal landforms, regardless of their drainage regime. Podzols in well drained moisture regimes also occur locally on colluvial, landslide, fluvial, ice contact stratified, and residual landforms, provided Eolian material B is present and surfaces are stable. The wetter Podzols occur locally on glaciolacustrine landforms in Banff. The landform materials may be either calcareous or noncalcareous. Podzolic soils occurring on calcareous materials frequently have a pH >5.5 within 25 cm from the top of the B horizon and are associated with Eutric and/or Melanic Brunisols.

THE CHERNOZEMIC ORDER

Steeply sloping, southerly-facing Montane and Subalpine grasslands and dry shrublands are dominated by Regosolic and Brunisolic soils with organo-mineral (Ah) surface horizons. The Ah horizons are of variable thickness but where they are 10 cm or more in thickness the soils have been mapped as Humic Regosols and Melanic Brunisols. There is some new evidence, based on data from our instrumented Mt. White grassland site (between Scotch Camp warden cabin and Snow Creek Pass), that some of these soils may, in fact, be Chernozemic.

Mean annual soil temperature from fall 1979 to fall 1980 was greater than 0°C for the instrumented pedon, which occurs at an elevation of nearly 2000 m. Morphological and chemical data for the pedon also support classification in the Chernozemic Order, specifically, the Orthic Dark Brown Subgroup. Depending upon the reliability of one year's temperature data and its extrapolation, Rego and Calcareous Dark Browns can also be expected. The pedon description and accompanying analyses for the instrumented grassland site are presented in the Wildflower 7 (WF7) Ecosite description, Chapter IV.

Steep, grassland and shrubland dominated slopes are common in the lower Athabasca River valley (Montane) and in several portions of the Front Ranges subprovince (Subalpine), particularly in eastern Banff. In the Front Ranges, there is a strong association with geomorphic materials derived from Mesozoic strata. Because the extent of Chernozemic soils on these slopes is thought to be of limited areal extent and the temperature data of these soils tentative, Chernozemic soils are not reflected in the Banff—Jasper Ecological Land Classification map legend.

THE CRYOSOLIC ORDER

Cryosolic soils represent the coldest soils found in Banff and Jasper. They have permafrost within 1 m and often within 50 cm of the ground surface. Cryosolic soils dominate many steep (30-70%), northerly-facing, forested slopes in the Front Ranges subprovince north of Banff townsite. They are confined primarily to morainal landforms consisting of medium textured, variably calcareous till derived from Mesozoic strata. Cryosolic soils occur in the Upper Subalpine from about 2200 m in Banff to as low as 1600 m in northern Jasper.

Regosolic Static Cryosols are most abundant. Their genesis is commonly influenced by solifluction which disrupts horizon development and mixes contrasting geomorphic materials in the active layer. Occasionally, buried organic and organo-mineral layers occur in the active layers, giving turbic phases. Orthic Static Cryosols occur on sites where the solifluction process is inconsequental. On a few undisturbed sites, altered, medium textured eolian material (Eolian material B) is present, resulting in yet thicker B horizons and soils classed as Brunisolic Static Cryosols. A feature common to these soils is the relatively thick (10-40 cm) organic layers (LFH horizons) mantling the mineral surface.

Cryosolic soils are generally imperfectly drained. However, a thin, saturated zone is frequently maintained at the frozen—unfrozen interface during thaw periods. This melt water usually seeps downslope over the frozen layer. Gley features are usually indistinct and partially masked by the inherently dark colored genetic material.

Gleyed Eutric Brunisols and, less frequently, Gleyed Cumulic Regosols are intimately associated with the Cryosolic soils. They occur along tract margins and in patches where permafrost is absent, probably only briefly during late summer. Gleyed Cumulic Regosols, like the Regosolic Static Cryosols, show the effects of solifluction.

Solifluction features, mainly lobes and benches, and a ragged, drunken forest appearance are common on landscape dominated by Cryosolic soils. They support stunted Engelmann spruce-subalpine fir forests, namely the Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/rock willow/white mountain heather (C24) v.t.s, with a nearly continuous feathermoss understory.

Achuff and Coen (1980) present data from a

Brunisolic Static Cryosol site on Mt. White in Banff. They recorded a mean annual permafrost temperature of -1.5°C at 100 cm and postulate that snow depth pattern throughout the year is particularly influential in maintaining the presence of permafrost. Distribution of Cryosolic soils on geomorphic material derived from Mesozoic strata suggests that some genetic material characteristics may also be important.

THE REGOSOLIC ORDER

Regosolic soils occur where active and recently active geomorphic processes of sufficient frequency and intensity inhibit pedogenic horizonation other than Ah horizon formation. They occur in all Ecoregions, on a variety of calcareous and noncalcareous geomorphic materials, on a variety of slopes, and under several different kinds of vegetation. Processes that modify landform surfaces and contribute to Regosolic soil maintenance are avalanching, soil creep, fluvial erosion and deposition, eolian deflation and deposition, windthrow of trees, sheet erosion, gully erosion, solifluction, and cryoturbation. Major landform building processes of recent age are also included. These are recent moraines, glaciofluvial floodplains, colluvial slopes, landslides, fluvial landforms, and eolian deposits. In some localities, shallow genetic materials overlying calcareous lithic layers also contribute to the occurrence of Regosolic soils.

Regosolic soils generally lack B horizons but in some localities may have thin (<5 cm) weakly developed Bm horizons. On actively eroding and aggrading sites, unaltered geomorphic material is often exposed at the surface. On some sites, thin organic layers and (under non-forested conditions) organo-mineral (Ah) horizons may develop. Regosolic soils of the Alpine, Alpine—Upper Subalpine ecotone, avalanched localities, grasslands, and dry shrublands frequently exhibit surface Ah horizons of varying thickness. In some cases, these horizons have been physically thickened by accretion of Ah material. Regosolic soils with surface Ah horizons <10 cm thick are classed as Regosols at the Great Group level (C.S.S.C. 1978b). In contrast Humic Regosols have surface Ah horizons 10 cm or more in thickness.

Cumulic Subgroups of these Great Groups generally have buried organic or organo-mineral horizons and, occasionally, buried B horizons. These indicate periods of relative stability followed by periods of genetic material accretion. In other cases, some geomorphic processes mix surface organic materials with subsurface mineral materials. Solifluction is a good example of such a process.

Regosolic soils are most often associated with Brunisolic soils under rapidly to moderately well drained conditions and where erosion and deposition have affected only portions of the landscape. On slopes characterized by grassland and dry shrubland, some of the soils classified as Humic Regosols may in fact be Rego Dark Browns in the Chernozemic Order as discussed previously. Under imperfectly to poorly drained conditions, Regosolic soils are often associated with Gleysolic and, less often, Organic soils. These are the Gleyed and Gleyed Cumulic Subgroups (C.S.S.C. 1978b). Evidence of gleying (i.e. dull colors and strong mottling) is only weakly expressed in the upper 50 cm of mineral soil.

THE GLEYSOLIC ORDER

Gleysolic soils occur under imperfectly to very poorly drained conditions on glacial, glaciolacustrine, fluvial, and fluviolacustrine landforms throughout all Ecoregions in Banff and Jasper. They generally occupy depressional landscape where seepage, surface water collection, and high water tables are important. A variety of moist to wet (hygric to hydric) vegetation is associated with Gleysolic soils.

Poorly aerated water saturates the soil for sufficiently long periods of time to result in reducing conditions. Manifestations of gleization are dull colors and/or strong mottling (C.S.S.C. 1978b). Gleysolic soils exhibit these features within 50 cm of the mineral surface. Rego Gleysols occur on sites where saturation is prolonged or where geomorphic activity has inhibited pedogenic horizonation. Orthic Gleysols, with B horizons, occur on stable sites where saturation periods are shorter or the seepage flow is more rapid and further from the surface.

Thin organic layers of moderately decomposed fen peat commonly mantle Gleysolic soils, except where mineral material is actively aggrading on fluvial, glaciofluvial, and fluviolacustrine landforms. Some Gleysolic soils also have thin organo-mineral (Ah) surface horizons. Rego Humic Gleysols and Orthic Humic Gleysols, with Ah horizons 10 cm or more thick, occur sporadically and are of minor importance on wetland areas.

Gleysolic soils are most often associated with gleyed Brunisolic, gleyed Podzolic, and Organic soils. Even though the gleyed Brunisolic and gleyed Podzolic soils occur under drainage regimes similar to those of the Gleysols, they often lack the mottling associated with intense reducing conditions.

THE ORGANIC ORDER

Organic soils occur most often in association with Gleysolic soils under poorly to very poorly drained conditions, primarily on glacial, fluvial, and fluviolacustrine landforms. The Organic members are the most poorly drained members of the association and are characterized by accumulation of 40 cm or more of primarily moderately decomposed organic material. Prolonged periods of ponding, with-

out mineral material sedimentation, and fen vegetation promote the accumulation of peat. Organic soils also occur on slopes of up to 15% where seepage is an important factor throughout much of the year.

The organic material is thought to be fen peat derived from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*), even though the fen vegetation has succeeded to open and closed forest in several areas. The peat is mainly moderately decomposed, hence the dominant Great Group is Mesisol. Subdominant humic and fibric layers and wood fragments also occur. Humic layers tend to be more common at low elevations, consequently Humisols occur sporadically in the Montane.

The peat accumulations rarely exceed 1.2 m in depth and the dominant Organic soils in Banff and Jasper are therefore Terric Mesisols. Thin mineral layers of fluvial and eolian origin are occasionally found included in lower portions of the organic layers. Underlying mineral materials are generally strongly gleyed.

METHODS OF SOIL DESCRIPTION AND ANALYSES

The necessary pedon and site information as suggested by Day et al. (1975) was recorded directly on computer coding forms using the procedures of Dumanski et al. (1975) and C.S.S.C. (1978a, b). The soils data and accompanying vegetation data were sorted and organized by computer as an aid to developing and refining the mapping legend.

FIELD EXAMINATION AND SOIL DESCRIPTION METHODS

The field work procedure involved initial stratification of the landscape by placing boundaries on aerial photographs followed by ground checking (field data collection) to refine map unit boundary locations and to corroborate interpretation of the landform, soil, and vegetation landscape components within map delineations. The observation sites were located on the aerial photographs as precisely as possible and pinpricks placed through the photograph so that locations could be annotated on the back with sample numbers. Thus, besides having UTM coordinates, each soil site (field checked and/or sampled) had an identified location on an aerial photograph. Field traverses were planned by examining the aerial photograhs and choosing a route that would verify the greatest number of map delineations and/or examine the delineations where the aerial photographic interpreter had questions requiring field verification.

Following ground checking and mapping procedures, various pedons were chosen to represent the soils of the Ecosites. These were described in detail on CanSIS forms and sampled for routine analysis in the laboratory.

CHEMICAL AND PHYSICAL ANALYTICAL METHODS

LABORATORY ANALYSES

Chemical and physical analyses were carried out after the samples were air dried and ground according to the routine procedures used by the Alberta Institue of Pedology (C.S.S.C. 1978c). These involved a determination of:

Soil Reaction; pH was determined with a pH meter using a 2:1 0.01 M $CaCl_2$ solution to soil ratio (Peech 1965).{3.11}[1]

Total Nitrogen; determined by the macro Kjeldahl-Wilforth-Gunning method (A.O.A.C. 1955). A mixture of HgO, $CuSO_4$, and K_2SO_4 (Kelpak) was used as a catalyst.

Calcium Carbonate Equivalent; inorganic carbon manometric method of Bascombe (1961).

Organic Carbon; by difference between total carbon and inorganic carbon. Total carbon was determined by dry combustion using an induction furnace (Allison et al. 1965) with a gasometric detection of evolved CO_2 (Leco model 577-100). {3.611}

Cation Exchange Capacity; by displacement of ammonium with sodium chloride (Chapman 1965) except that NH_4+ ion electrode is used to detect the displaced ammonium ion. {3.321}

Exchangeable Cations; extraction by neutral N NH_4OAC (A.O.A.C. 1955) with K, Mg, Na, and Ca determined by atomic absorption spectroscopy. {3.53, 3.531}

Sodium Pyrophosphate Extractable Iron and Aluminum; by McKeague (1967) method. The determination of Fe and Al was done by atomic absorption spectroscopy. {3.53,3.531}

Particle Size Distribution; by the pipette method of Kilmer and Alexander (1949) as modified by Toogood and Peters (1953), except that car-

[1]The numbers in {} indicate the method in C.S.S.C. (1978c).

bonates were not removed prior to dispersion.

Liquid limit, Plastic limit, and Plasticity Index; by the method outlined by ASTM (1970). {2.61, 2.62, 2.63}

One-third and fifteen Bar Moisture; by the pressure plate and pressure membrane methods (U.S. Salinity Laboratory Staff 1954). {2.44}

Bulk Density; by the soil clod method using Saran (C.S.S.C. 1978c). The samples were oven dried and weighed. Calculations were based on air dry volume. Values reported are the arithmetic mean of 3 to 5 determinations per horizon. {2.221}

FIELD TESTS

Percolation; by the method suggested by the Alberta Department of Manpower and Labour (1972). This consists of digging a hole to the depth of interest and saturation for 24 hours before measuring the rate of drop of the water level in the hole.

Infiltration; by the double ring method with a constant head apparatus as suggested by Adams et al. (1957).

VEGETATION: INTRODUCTION AND METHODS

FIELD SAMPLING

One vegetation study objective was to provide vegetation resource data for integration into the Ecological Land Classification. The methods are therefore appropriate to the constraints of a 1:50,000 mapping program. Polygons of homogeneous composition were initially outlined on air photos. Selected polygons were then examined in the field. Single sample plots were established in areas representative of the predominant vegetation of the polygon. Each plot was located in a homogeneous area with avoidance of obvious ecotones, edge effects or environmental discontinuities (e.g. rock outcrops or drainage ways). Plots were generally 20 X 20 m in forested vegetation, 15 X 15 m in shrubby vegetation and 10 X 10 m in herbaceous and dwarf shrub vegetation. Smaller plots (5 X 5 m or 1 X 1 m) were sometimes necessary to keep the plot boundaries within a homogeneous area, as in some intricately patterned Alpine tundra.

Within each plot, canopy cover (Daubenmire 1959) was estimated to the nearest percent both for individual species and for each layer. Plants present with <1% cover were considered to have 0.5% cover. Epiphyte cover was not estimated; the species were merely noted as being present and all were assigned 0.5% cover. The layers recognized were: 1)Tree layer: woody plants >5 m tall. This layer was often divided into two layers where two tree height classes existed, 2)Tall Shrub layer: woody plants 2 to 5 m tall, 3)Low Shrub layer: woody plants 0.5 to 2 m tall, 4)Herb-Dwarf Shrub layer: woody plants <0.5 m tall and all herbs regardless of height, and 5)Bryoid layer: terrestrial lichens and bryophytes. Cover values were also estimated for ground litter (LFH), rocks and stones, exposed mineral soil, deadfall, and water. Usually, one of the largest trees in the plot was measured for height and diameter at breast height (dbh) and cored with an increment corer to determine its age. In addition, the average tree canopy height and the mean and range of dbh were estimated.

Physical environmental factors noted included: elevation, slope, aspect, topographic position, relief shape, landform, soil subgroup, and drainage class. Each plot was also rated on a moisture regime (hygrotope) scale (Table 7).

Voucher specimens were collected and are deposited in the herbaria of : Northern Forest Research Centre (CAFB), University of Alberta (ALTA), New York Botanical Garden (NY), Agriculture Canada (DAO), and the National Museum of Canada (CAN). Nomenclature for vascular plants follows primarily Moss (1959) and Hitchcock and Cronquist (1973), for hepatics Stotler and Crandall-Stotler (1977), for mosses Crum et al. (1973), and for lichens Hale and Culberson (1970) and Hawksworth et al. (1980).

CLASSIFICATION

The vegetation was classified initially into physiognomic classes: Closed Forest (C), Open Forest (O), Shrub (S), Low Shrub-Herb (L), and Herb-Dwarf Shrub (H). Closed Forests are those in which the distance between tree

Table 7 Ecological moisture regime clauses (Walmsley et al. 1980).

Class	Usual Soil Drainage
xeric - very dry, little precipitation or high evapotranspiration, very low available water storage capacity (AWSC)	very rapid
subxeric - dry, low AWSC	rapid
mesic - moist, intermediate to high AWSC	well to moderately well
subhygric - moist to wet, variable AWSC, seasonal seepage	imperfect
hygric - wet, variable AWSC, permanent seepage	poor
subhydric - wet, variable AWSC, excess water most of time	very poor
hydric - very wet, standing water constantly	-

crowns is not more than twice the mean crown diameter. This generally corresponds to a lower limit of tree cover of 15 to 20%. In Open Forests the distance between the crowns is 2X to 5X the mean crown diameter and tree cover is generally between 5% and 15 to 20%. Vegetation with <5% tree cover is not considered forested. Within these physiognomic classes, the classification is based primarily on stratal dominance (Whittaker 1973b) and characteristic combinations of species. Importance or dominance is determined by cover values and thus is a quantitative attribute. The vegetation samples are grouped on the basis of shared characteristics into abstract units called vegetation types (v.t.s). The v.t.s are viewed as "noda" (Poore 1962) along a vegetational gradient or "coenocline" (Whittaker 1967). The v.t. is of the same order of magnitude as the "association" of the Zurich-Montpellier approach (Westhoff and van der Maarel 1973) or the "biogeocoenose" of Sukachev (Sukachev and Dylis 1964), although the bases and methods of recognition differ. V.t.s were delineated by tabular comparison (Mueller-Dombois and Ellenberg 1974) and by both indirect ordination (Wisconsin ordination; Cottam, et al. 1974) and direct ordination (gradient analysis, Whittaker 1973a). Both seral and climax vegetation types were recognized. The plants used to name the v.t.s are usually layer dominants. A hyphen (-) separates species in the same layer; a virgule (/) separates layers.

ECOREGIONS

Vegetation is used as the basis for the definition of Ecoregions (Zones) in the Ecological Land Classification. Ecoregional divisions reflect macroclimate and thus, vegetation features, which reflect primarily climatic factors rather than for example edaphic factors, are used to define the Ecoregions. From low to high elevation, three Ecoregions are recognized: Montane, Subalpine and Alpine (Figs. 21, 22). Ecoregion is conceptually similar to the zone of Daubenmire (1968) and La Roi (1975), the biogeoclimatic zone of Krajina (1965) and Kojima (1981), the ecoregion of Strong and Leggat (1981), and the biophysical region of Lacate (1969). The Montane Ecoregion is characterized by v.t.s dominated by *Pseudotsuga menziesii*, *Picea glauca* and *Populus tremuloides* and by grasslands. Characteristic also is intermittant snow cover as a result of chinooks. Typical v.t.s include Douglas fir/hairy wild rye (C1), white spruce/fern moss (C2), lodgepole pine/juniper/bearberry (C3), aspen/hairy wild rye-peavine (C16) and junegrass-pasture sage-wild blue flax (H6). The altitude of the Montane Ecoregion ranges from the lowest elevations in the parks (about 1350 m in Banff and 1000 m in Jasper) to about 1600 m in Banff and 1350 m in Jasper. The boundary is slightly lower on northerly aspects and slightly higher on southerly aspects.

The Subalpine Ecoregion occurs at altitudes above the Montane Ecoregion and below the unforested Alpine Ecoregion. The Subalpine Ecoregion is further divided into Lower Subalpine and Upper Subalpine. The predominant vegetation of the Lower Subalpine is closed coniferous forest. Mature forest is dominated by *Picea engelmannii* and *Abies lasiocarpa*. Introgressive hybrids between *Picea engelmannii* and *Picea glauca* are common at lower altitudes of the Lower Subalpine. *Pinus contorta* forests are also common at lower altitudes. Typical v.t.s include lodgepole pine/buffaloberry/showy aster (C6), lodgepole pine/buffaloberry/twinflower (C19), Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/false azalea (C14). The upper altitudinal boundary of the Lower Subalpine is generally about 2000 m in Banff and 1900 m in Jasper.

The Upper Subalpine portion of the Subalpine Ecoregion is broadly ecotonal between Lower

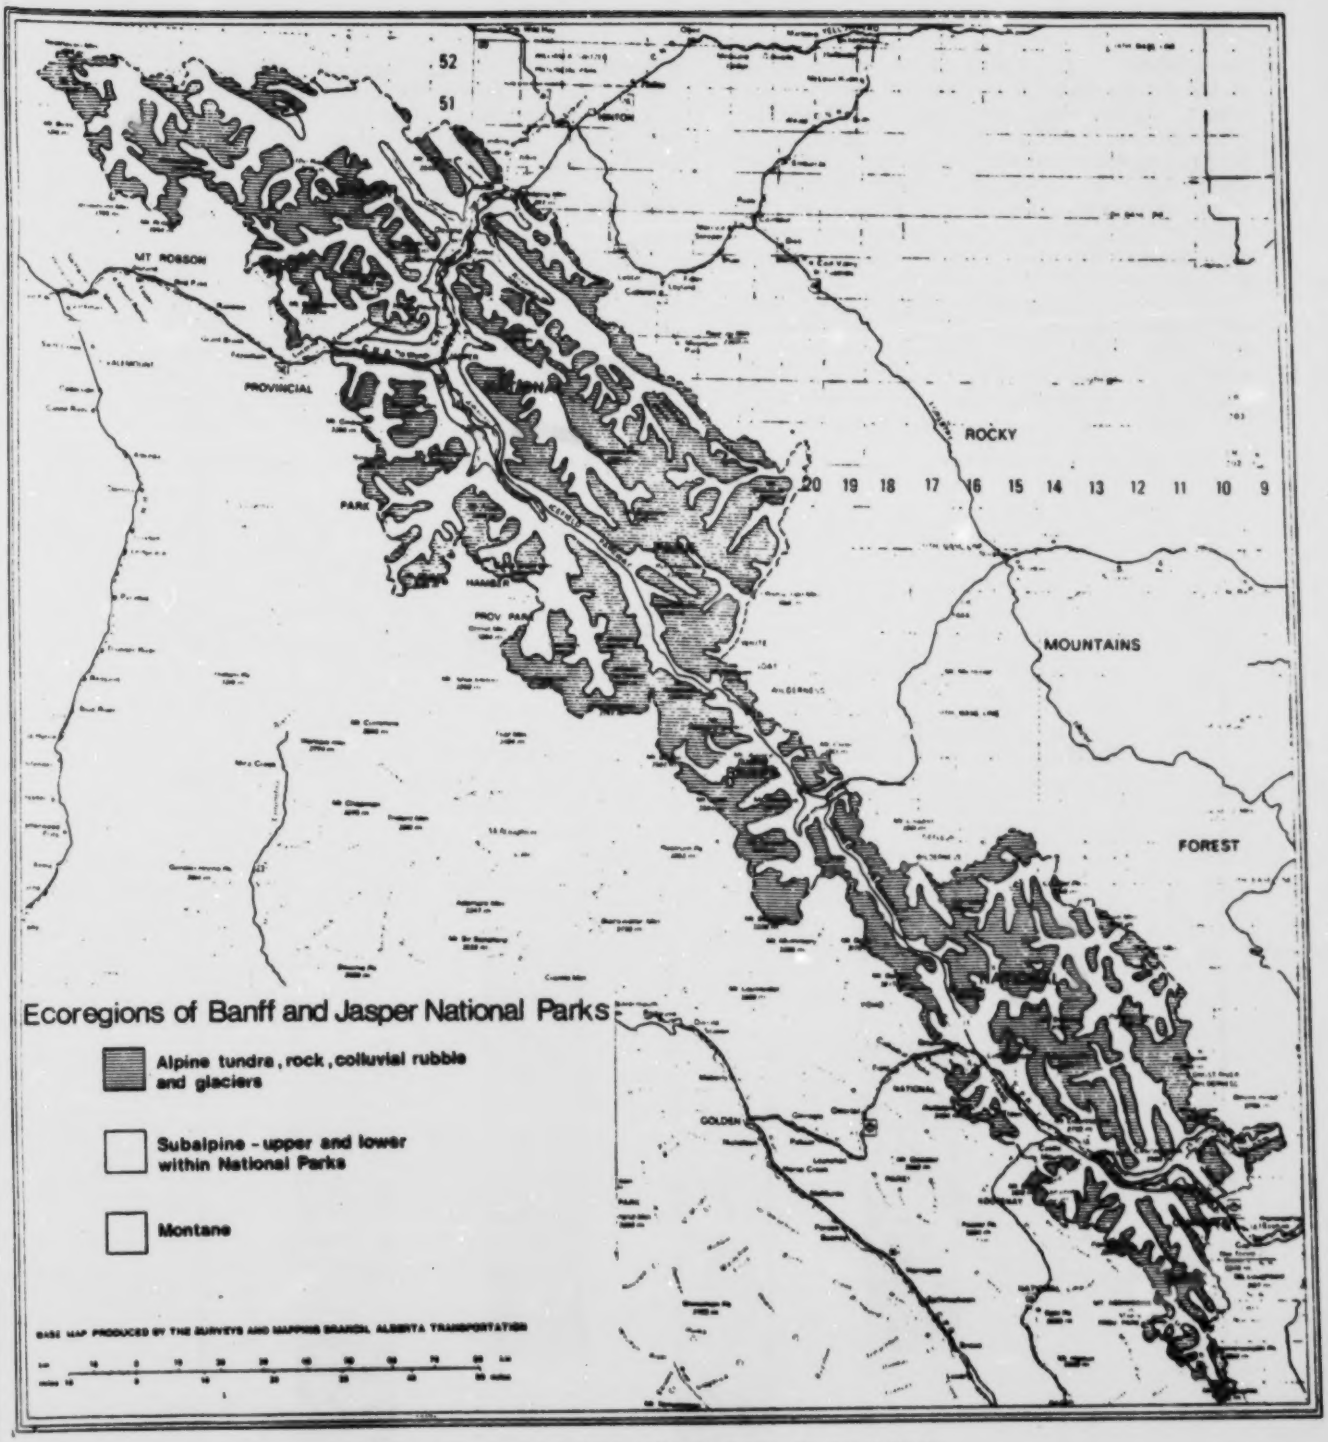

Figure 21 Ecoregions of Banff and Jasper National Parks.

Subalpine closed forest and treeless Alpine tundra. Compared to the Lower Subalpine, the Upper Subalpine climate is cooler and wetter, with greater snowfall, later snowmelt, and a shorter growing season. Greater wind speed also appears to be a significant climatic factor. Perhaps most characteristic are the open forests and stunted tree growth forms

(krummholz). The closed forests which occur in the Upper Subalpine typically contain some Alpine floristic elements, such as *Phyllodoce glanduliflora* in Engelmann spruce-subalpine fir/heather/feathermoss (C34) and occur at lower altitudes within the Upper Subalpine, often on warmer, southerly aspects. In the southern part of Banff, subalpine larch-subalpine fir/grouseberry-everlasting (C23) forests are characteristic of the Upper Subalpine. *Pinus contorta* is generally absent and forests are usually dominated by *Picea engelmannii* and *Abies lasiocarpa*. Typical v.t.s include Engelmann spruce-subalpine fir/heather (O10), Engelmann spruce-subalpine fir/valerian-fleabane (O9), Engelmann spruce-subalpine fir/grouseberry (C15) and Engelmann spruce-subalpine fir/rock willow/white mountain heather (C24). The upper altitudinal boundary to the Alpine Ecoregion is about 2300 m in Banff and 2200 m in Jasper.

The treeless Alpine Ecoregion occurs at elevations above the Upper Subalpine and reflects a cold, harsh climate. Alpine vegetation typically forms a complex, fine-scale mosaic in which microclimatic variations are reflected by marked changes in dominant species. Significant microclimatic factors include aspect, wind exposure, time of snowmelt, soil moisture, and snow depth. The most common v.t.s are heather-everlasting (L5) and mountain

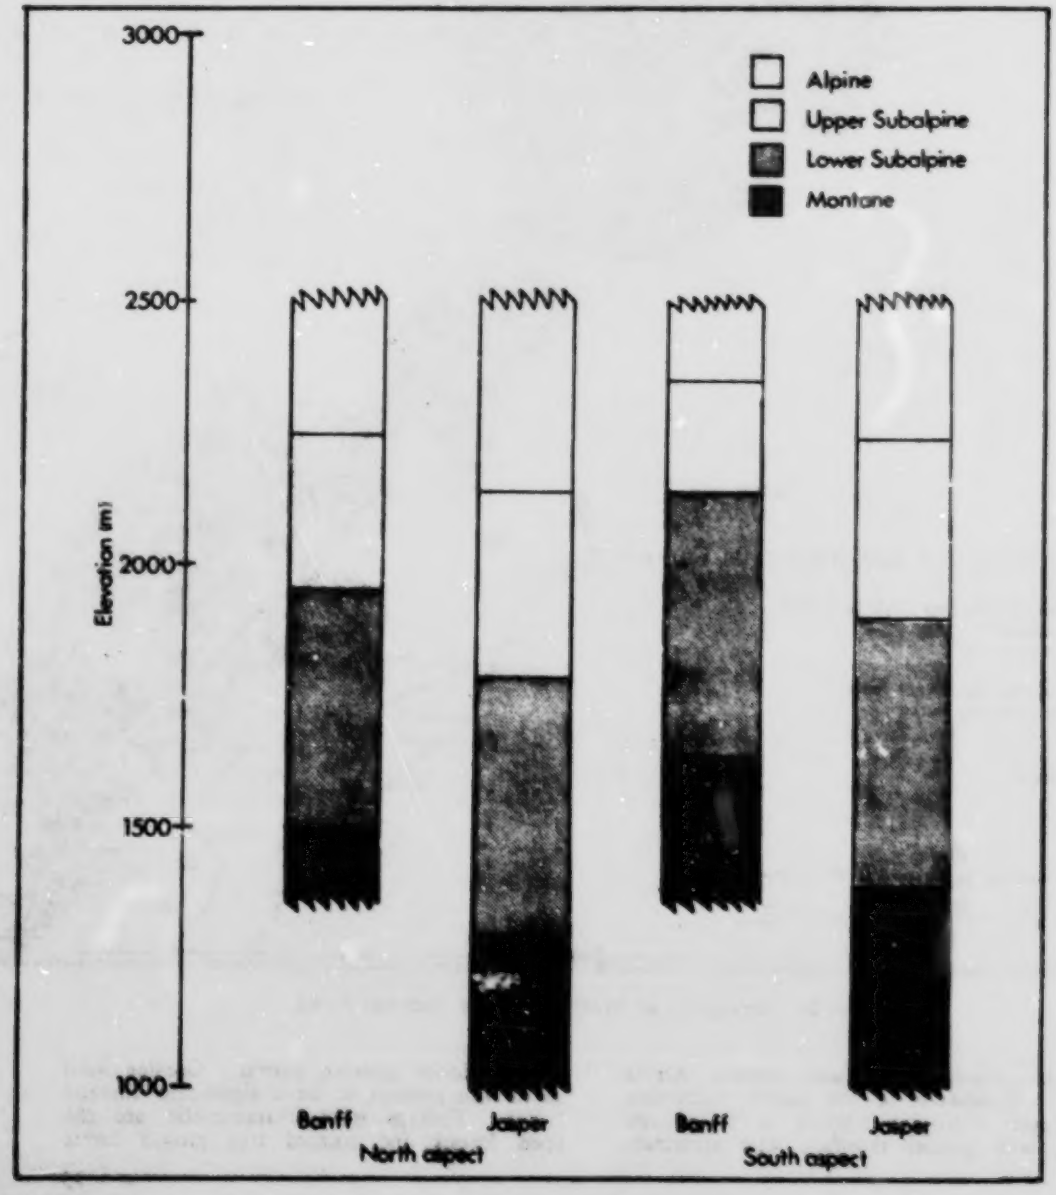

Figure 22 Elevation ranges of Ecoregion and Ecoregion subunits in Banff and Jasper National Parks.

avens-snow willow-moss campion (H1) in wind exposed sites and white mountain heather-mountain avens-snow willow (L4) in moderately deep snowbed sites. The highest altitude communities are usually saxicolous lichen (H12) on rocks and shallow soil.

VEGETATION TYPE DESCRIPTIONS

I.G.W. Corns and P.L. Achuff

C1: *Pseudotsuga menziesii/Elymus innovatus*

(Douglas fir/hairy wild rye)

Environment: The C1 v.t. occurs on subxeric mostly Montane sites (1150-1400 m J, 1300-1700 m B) on moderate to steep slopes and southerly aspects in the Bow River valley in Banff and the Athabasca River valley in Jasper. The soils are rapidly to well drained Eutric Brunisols and Regosols on colluvial and morainal landforms.

Vegetation: *Pseudotsuga menziesii* is the dominant canopy tree (Plate 6) with cover ranging from 15 to 70%, but usually 30 to 40% (Table 8). *Pinus contorta* and *Picea glauca* are often present with low cover in the tree layer. The shrub layer has a total cover of 10 to 25%, with *Juniperus communis* (1-15%), *Shepherdia canadensis* (1-5%), *Rosa acicularis* (<5%) and *Spiraea lucida* (≤5%) most common. *Elymus innovatus* (5-20%) and, in Banff, *Calamagrostis rubescens* (10-35%) dominate the herb-dwarf shrub layer. *Aster conspicuus* (5-10%) occurs frequently and *Fragaria virginiana*, *Achillea millefolium* and *Arctostaphylos uva-ursi* occur frequently but with cover usually <5%. The bryoid layer is sparse with small amounts of *Hylocomium splendens*, *Hypnum revolutum*, *Drepanocladus uncinatus*, and *Peltigera aphthosa*. Epiphytes are scarce with small amounts of *Letharia vulpina* usual.

The C1 v.t. is mature successionally with many stands 100 to 300 years old. *Pseudotsuga menziesii* regeneration of all size classes is commonly present indicating a self-perpetuating tree layer. Large, old *Pseudotsuga menziesii* with thick bark and several fire scars indicate that fires were a common occurrence in this type. Some stands were partially cut in the past.

The C1 v.t. differs from C5 in that C1 occurs on drier, often lower elevation sites, *Picea glauca* is not codominant in the tree layer, the shrub layer has greater cover, and the bryoid layer has little cover.

Other Studies: In Alberta, similar types have been described by Kondla (1978) in Kananaskis Provincial Park (Douglas fir/common juniper, Douglas fir/common juniper-buffaloberry), Jacques and Legge (1974) in the Kananaskis area (*Pseudotsuga menziesii/Calamagrostis rubescens-Elymus innovatus*), La Roi (1975) in Jasper (*Pseudotsuga menziesii/Elymus innovatus/Penstemon procerus/Cetraria islandica*), Stringer and La Roi (1970) in Banff (*Pseudotsuga menziesii/Calamagrostis rubescens-Elymus innovatus*) and Jasper (*Pseudotsuga menziesii/Elymus innovatus*), and Duffey (1971, Douglas fir) and Ogilvie(1971, Douglas fir) in the Porcupine Hills. The *Pseudotsuga menziesii/Elymus innovatus/Hylocomium splendens* type of LaRoi (1975) in Jasper is more mesic than most C1 stands. In central British Columbia, similar types have been described by Beil (1974, *Pseudotsuga menziesii/Calamagrostis rubescens*), Kuchar (1978) in Yoho National

Park (Douglas fir/pine grass-showy aster), Brayshaw (1965, *Pseudotsuga menziesii/Calamagrostis rubescens*, *Pseudotsuga menziesii/Arctostaphylos-Calamagrostis rubescens*), McLean (1970, Tisdale and McLean 1957, McLean and Holland 1958; *Pseudotsuga menziesii/Calamagrostis rubescens*), and Kujala (1945, *Pseudotsuga menziesii/Arctostaphylos-Calamagrostis*). Daubenmire and Daubenmire (1968) have described a *Pseudotsuga menziesii/Calamagrostis* type from northern Idaho and eastern Washington. In Montana, the *Pseudotsuga menziesii/Calamagrostis rubescens* type of Pfister et al. (1977) is similar, although floristic differences in nondominant species are apparent, and *Elymus innovatus* is absent.

C2: *Picea glauca/Thuidium abietinum*

(white spruce/fern moss)

Environment: The C2 v.t. occurs on mesic, Montane (1000-1300 m) sites of various slopes with northerly aspect, mostly in the east gate area of Jasper. The soils are well to rapidly drained Cumulic Regosols and Orthic Eutric Brunisols developed on highly calcareous eolian and fluvial landforms.

Vegetation: *Picea glauca* is the dominant tree (Plate 7) with 15 to 60% cover (Table 9). *Betula papyrifera* is occasionally present and *Pinus contorta* is usually absent. The shrub layer has generally <10% cover with *Rosa acicularis* (<5%) and *Shepherdia canadensis* (<3%) as the usual dominants. The cover of the herb-dwarf shrub layer is generally <10% but sometimes as high as 15%. Dominant species are *Elymus innovatus* (1-10%), *Linnaea borealis* (1-8%), and *Pyrola secunda* (<3%). *Clematis verticellaris* is present with low cover in most stands. The bryoid layer is dominated by the calciphile *Thuidium abietinum* (20-95%) and by *Hylocomium splendens* (<15%). Terrestrial and epiphytic lichens are scarce.

Successionally, C2 is advanced to mature with most stands 100 to 200 and occasionally 300 years old. *Pseudotsuga menziesii* is invading some sites or may be present as a relict of a previous stand.

The C2 v.t. is distinguished from C13 by the dominance in C2 of *Thuidium abietinum* rather than *Hylocomium splendens*. C2 differs from C26 and C27 in having a shrub layer with <5% cover and a sparse herb-dwarf shrub layer (Table 10). The C37 v.t. differs having well developed shrub and herb-dwarf shrub layers and *Hylocomium splendens* as the dominant bryophyte. Also, C37 occurs at elevations >1300 m where loessal veneers are shallow or absent. Intergrades between C2 and C26, C27 or C37 occur.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other Studies: Dowding (1929) described similar forests in the Brule Lake area north of Jasper.

C3: *Pinus contorta/Juniperus communis/Arctostaphylos uva-ursi*

(lodgepole pine/juniper/bearberry)

Environment: The C3 v.t. occurs on subxeric to mesic, Montane to Lower Subalpine sites (1030-2000 m) on gentle to steep slopes of southerly and westerly aspect. The soils are rapidly to well drained Eutric Brunisols and Regosols on morainal, colluvial, fluvial, and glaciofluvial landforms.

Vegetation: *Pinus contorta* (15-40%) dominates the tree layer (Table 11, Plate 8). *Picea glauca* occurs frequently but with low cover (<5%). The moderately dense shrub layer (15-35%) is dominated by *Juniperus com-*

Table 10 A comparison of four *Picea glauca* v.t.s. showing dominant species by layer.

Veg. type	Tree layer	Shrub layer	Bryoid layer
C2	*Picea glauca*	<10% cover	*Thuidium abietinum*
C26	*Picea glauca*	>10% cover *Shepherdia canadensis*	*Thuidium abietinum*
C27	*Picea glauca*	>10% cover *Rosa acicularis*	*Thuidium abietinum*
C37	*Picea glauca*	>10% cover *Shepherdia canadensis*	*Hylocomium splendens*

munis (5-25%), *Shepherdia canadensis* (5-15%), and *Rosa acicularis* (1-3%). *Arctostaphylos uva-ursi* (10-25%) dominates the herb-dwarf shrub layer. *Linnaea borealis* (3-8%) and *Elymus innovatus* (5-15%) are also important. *Fragaria virginiana*, *Hedysarum sulphurescens* (in Banff), *Zygadenus elegans*, and *Solidago decumbens* occur with low cover but high frequency. Bryoid layer cover is low (<1-15%) with small amounts of *Drepanocladus uncinatus*, *Pleurozium schreberi*, *Hylocomium splendens*, and *Dicranum* spp. Epiphytes are sparse with *Letharia vulpina* most common.

Stand age is 75 to 200 years. Tree regeneration is preponderantly *Pinus contorta* and thus, it appears to be a climax species on these sites. The C3 v.t. is advanced to mature successionally.

The C3 v.t. is closely related to C6, C9, and C19 and intergrading stands occur. Table 12 compares C3 and four other *Pinus contorta* v.t.s. The C3 v.t. differs in having the herb-dwarf shrub layer dominated by *Arctostaphylos uva-ursi* rather than *Aster conspicuus* (C6), *Vaccinium caespitosum* (C9) or *Linnaea borealis* (C19). The C3 also has lower *Shepherdia canadensis* cover than C6 or C19, a subxeric moisture regime, and *Pinus contorta* regeneration.

Other Studies: Vegetation types similar to C3 have been described widely from the southern Yukon to northern Wyoming. In Alberta, similar types have been described by Ogilvie (1976, *Picea/Arctostaphylos*), Trottier and Scotter (1973) in Banff (*Pinus contorta/Juniperus communis-Arctostaphylos uva-ursi*), Lesko and Lindsay (1973) in the west central Alberta foothills (lodgepole pine/bearberry), La Roi (1975) in Jasper (*Pinus contorta/Juniperus communis/Elymus innovatus/Arctostaphylos uva-ursi/Brachythecium salebrosum*, *Pinus contorta/Shepherdia canadensis/Elymus innovatus/Arctostaphylos uva-ursi*), Hettinger (1975) in Jasper (*Pinus contorta* dominated stands of the *Pseudotsuga menziesii/Juniperus communis/Calamagrostis purpurascens* type), and La Roi and Hnatiuk (1980, *Pinus*

contorta/Shepherdia canadensis/Arctostaphylas uva-ursi) in Banff and Jasper. Mackenzie-Grieve (1970) described similar *Pinus-Populus/Shepherdia-Arctostaphylos* vegetation from the Red Deer River area east of Banff. In British Columbia, similar types have been described by Wali and Krajina (1973, *Cladonio (gracilis)-Arctostaphylo (uvae-ursi)-Vaccinio (myrtilloidis)-Pinetum contortae*), Illingworth and Arlidge (1960, *Pinus contorta/Calamagrostis-Arctostaphylos*, *Pinus contorta/Arctostaphylos*-lichen), Raup (1934, dry pine woods), Beil (1974, *Pinus contorta/Calamagrostis rubescens*), Brayshaw (1965, *Pinus contorta/Arctostaphylos-Calamagrostis rubescens*), and Kujala (1945, *Pinus contorta/Arctostaphylos-Calamagrostis*). Orloci and Stanek (1979) described a *Pinus-Arctostaphylos-Festuca* type from the southern Yukon. Hoffman and Alexander (1976) described a *Pinus contorta/Arctostaphylos uva-ursi* type from northern Wyoming.

C4: *Picea glauca/Rosa acicularis/Equisetum arvense*

(white spruce/prickly rose/horsetail)

Environment: The C4 v.t. occurs on subhygric to hygric sites mostly in the Montane Ecoregion (usually <1500 m; 1000-1330 J , to 1530 B) on gentle slopes of various aspects in Banff and Jasper. The soils are imperfectly to poorly drained Gleysolics, Regosolics, and Organics on fluvial landforms.

Vegetation: This closed forest type has a tree layer with 20 to 55% cover composed almost entirely of *Picea glauca* (Table 13). The shrub layer is well developed (10-35% cover) and is dominated by *Rosa acicularis* (5-15%) with lesser amounts of *Cornus stolonifera* (3%) and *Alnus tenuifolia* (5%) in Jasper and of *Ribes lacustre* (1%) in Banff. Herb-dwarf shrub cover is 35 to 70% with *Equisetum arvense* (30-50%) dominant (Plate 9). Also of common occurrence are *Equisetum pratense* (5-15%), *Linnaea borealis* (5%), *Mitella nuda* (1%), *Equisetum scirpoides* (5%), and *Pyrola secunda* (<1%). Bryoid cover is 20 to 60% with *Hylocomium splendens* (15-50%) dominant. Ground lichens and epiphytes are sparse.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The C4 v.t. is mature successionally with stands 100 to 225 years old. *Picea glauca* regeneration is common in the shrub layers.

The C4 v.t. is similar to C32, but can be distinguished by occurring on wetter, generally Montane (<1500 m) sites, by having a denser shrub layer dominated by *Rosa acicularis, Cornus stolonifera*, and *Alnus tenuifolia*, and by the usual absence of *Arnica cordifolia, Elymus innovatus*, and *Mertensia paniculata*.

Other Studies: Similar vegetation (floodplain spruce forests) was described in northern Alberta and southern Northwest Territories along the Peace, Slave, and Mackenzie rivers by Raup (1934, 1946, 1947) and in the Alberta foothills by Lesko and Lindsay (1973, white spruce/horsetail association). In the Alberta Rocky Mountains, similar vegetation was described for Jasper by La Roi (1975, *Picea glauca-Picea mariana/Lonicera involucrata/Equisetum arvense/Equisetum scirpoides/Hylocomium splendens*), Kuchar (1972, lowland white spruce forest) and for Banff and Jasper by Ogilvie (1976, *Picea/Equisetum* association), and Beil (1974, *Picea glauca/Equisetum arvense*). Kuchar (1978) described a similar spruce/horsetail type in Yoho National Park and Pfister et al. (1977) encountered similar forests (*Picea/Equisetum arvense*) in Montana.

C5: *Picea glauca-Pseudotsuga menziesii/Hylocomium splendens*

(white spruce-Douglas fir/feathermoss)

Environment: The C5 v.t. occurs on mesic, Montane to Lower Subalpine sites (1250-1650 m) on various slopes and northerly aspects along the Athabasca River in Jasper and along the Bow River and Lake Minnewanka in Banff. The soils are well drained Orthic Eutric Brunisols, Regosols, and Brunisolic Gray Luvisols on fluvial and morainal landforms.

Vegetation: The tree layer is dense (Plate 10) and composed of *Picea glauca* (20-40%) and *Pseudotsuga menziesii* (20-40%) often in approximately equal amounts (Table 14). The shrub layer is sparse (<10%) with *Rosa acicularis* and *Shepherdia canadensis* having low cover but high frequency. The herb-dwarf shrub layer is also sparse (≤10%) and usually contains *Pyrola secunda* (<1%), *Linnaea borealis* (<5%), *Aster conspicuus* (<5%), *Cornus canadensis* (<5%), and *Elymus innovatus* (<3%). The bryoid layer has high cover (50-90%) and is dominated by *Hylocomium splendens* (30-75%) and *Peltigera aphthosa* (3-5%) with lesser amounts of *Pleurozium schreberi, Ptilium crista-castrensis, Drepanocladus uncinatus*, and *Peltigera canina*. Epiphytes are in moderate abundance with *Letharia vulpina* and *Parmelia sulcata* common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, C5 is mature with stands 100 to 300 years old.

The C5 v.t. differs from C1 in occurring on more mesic sites often at higher elevation, the shrub layer has less cover (<10%) and the bryoid layer, especially *Hylocomium splendens*, has greater cover.

Other Studies: Kuchar (1978) described a similar white spruce-Douglas fir forest from Yoho National Park in British Columbia. A related type (moss association) is described from southern British Columbia by Bell (1965) but has *Tsuga heterophylla* instead of *Picea glauca* codominant with *Pseudotsuga menziesii*.

C6: *Pinus contorta/Shepherdia canadensis/Aster conspicuus*

(lodgepole pine/buffaloberry/showy aster)

Environment: The C6 v.t. occurs on mesic Montane to Lower Subalpine sites (1400-1800 m B, 1150-1720 m J) on moderate slopes of southerly and westerly aspect. The soils are well to rapidly drained Eutric Brunisols, Regosols, and Brunisolic and Orthic Gray Luvisols on morainal, fluvial, colluvial, and glaciofluvial landforms.

Vegetation: The tree layer is closed (30-55%) and dominated by *Pinus contorta* (25-45%) (Table 15). *Picea* spp. are also often present with cover ≤10%. The moderately dense shrub layer (20-40%)(Plate 11) is dominated by *Shepherdia canadensis* (15-30%). Other common shrubs are *Juniperus communis* (1-5%), *Rosa acicularis* (10-20%) and *Spiraea lucida* (1%). The herb-dwarf shrub layer, with a total cover of 40 to 60%, is dominated by *Aster conspicuus* (10-20%) and *Elymus innovatus* (10-15%), or *Calamagrostis rubescens* (10-20%) in some Banff stands. *Linnaea borealis* (3-5%), *Arnica cordifolia* (1-5%), and *Arctostaphylos uva-ursi* (1-3%) are common and *Pyrola secunda*, *Fragaria virginiana* and *Epilobium angustifolium* occur with high frequency but low cover. The bryoid layer has a total cover of 30 to 60% and is dominated by *Hylocomium splendens* (10-30%), *Pleurozium schreberi* (10-25%), and *Peltigera aphthosa* (1-3%). Epiphytes are scarce with *Letharia vulpina*, *Alectoria* spp., and *Usnea* spp. most common.

Stands in C6 are mostly 60 to 100 years old and of fire origin. Tree regeneration is mostly *Picea* spp. and C6 is intermediate to advanced successionally. Successional development to C31, C13, or C37 appears likely.

The C6 v.t. is closely related to C3, C18, and C19 and intergrading stands occur. Table 12 compares C6 and four other *Pinus contorta* v.t.s. The C6 v.t. differs from the other v.t.s in having the herb-dwarf shrub layer dominated by *Aster conspicuus* rather than *Linnaea borealis* (C19), *Vaccinium scoparium* (C18), or *Arctostaphylos uva-ursi* (C3). The C3 v.t. also differs from C6 in having lower *Shepherdia canadensis* cover, higher *Juniperus communis* cover, and *Pinus contorta* regeneration rather than *Picea* spp.

Other Studies: Similar forests were described for Alberta by Kirby and Ogilvie (1969) in the Kananaskis area (young *Pinus contorta/Hylocomium-Cornus* type) and by Kondla (1978) also for the Kananaskis area (pine/buffaloberry-feathermoss type). Cormack (1953) in the southern Alberta foothills described similar forests as seral to spruce-fir climax. In Banff, Ogilvie (1976) described a similar pine dominated *Picea-Abies/Calamagrostis* type and in Jasper Hettinger (1975) described similar vegetation as seral to a *Pseudotsuga menziesii/Elymus innovatus* type. La Roi (1975) also described a similar type in Jasper (*Pinus contorta/Shepherdia canadensis/Rosa acicularis/Arnica cordifolia/Linnaea borealis/Pleurozium schreberi*). In Banff and Jasper, La Roi and Hnatiuk (1980) described a similar *Pinus contorta/Shepherdia canadensis/Elymus innovatus* type. Similar types have been de-

scribed in British Columbia by Kuchar (1978) in Yoho National Park (lodgepole pine/buffaloberry/pinegrass), Tisdale and McLean (1957) in central British Columbia (*Pinus/Calamagrostis*), and by Illingworth and Arlidge (1960) in south central British Columbia *(Pinus contorta/ Calamagrostis).*

C8: *Picea mariana-Pinus contorta/Salix myrtillifolia/Carex vaginata*

(black spruce-lodgepole pine/willow/sedge)

Environment: The C8 v.t. occurs on hygric Montane to Lower Subalpine sites (1230-1700 m) on level to gently sloping northerly aspects in Jasper and northern Banff. The soils are Gleysolics and Organics occurring on morainal landforms.

Vegetation: The tree layer is closed (20-50%)(Plate 12) and is dominated by *Picea mariana* (10-40%) and *Pinus contorta* (5-10%)(Table 16). The shrub layer has a total cover of 20 to 40% and includes *Salix myrtillifolia* (5-10%) and *Ledum groenlandicum* (5-20%). The herb-dwarf shrub layer has 15 to 40% cover and is dominated by *Carex vaginata* (2-5%), *C. capillaris* (1%), and *Arctostaphylos rubra* (3%). *Petasites palmatus, Equisetum arvense, E. scirpoides,* and *Linnaea borealis* have cover ≤1% but high frequency. The bryoid layer covers 50 to 75% of the hummocky ground surface. Important species are *Aulacomnium palustre* (5-30%) and *Tomenthypnum nitens* (5%) in wetter microsites, and *Hylocomium splendens* (10-50%) and *Pleurozium schreberi* (5-20%) in drier microsites on hummock tops. *Peltigera aphthosa* is common but with cover <1%. Epiphytes are generally scarce.

Stands are 100 to 150 years old. *Picea mariana* regeneration is common and C8 is advanced to mature successionally.

The closed tree canopy and the occurrence of *Pinus contorta* in C8 distinguish it from O11.

Other Studies: Laidlaw (1971) described a similar type (*Picea mariana-Pinus contorta/ Ledum groenlandicum-Salix* spp./*Carex* spp./ *Ditrichum flexicaule*) from Jasper.

C9: *Pinus contorta/Vaccinium caespitosum*

(lodgepole pine/dwarf bilberry)

Environment: The C9 v.t. occurs on mesic to subxeric, Montane to Lower Subalpine sites (1400-1750 m) on nearly level slopes of southerly aspect in Banff. The soils are well drained Dystric and Eutric Brunisols, and some Orthic Gray Luvisols on fluvial, glaciofluvial, and glaciolacustrine landforms, primarily along the Bow and Spray River valleys.

Vegetation: *Pinus contorta* (25-40%) dominates the closed tree layer (Table 17). The shrub layer has a total cover of 5 to 15% with *Shepherdia canadensis* (6%), *Rosa acicularis* (1%), and *Juniperus communis* (1%) dominant. The herb-dwarf shrub layer has moderate to dense cover (30-60%) and is dominated by *Vaccinium caespitosum* (10-25%). Other leading species include *Elymus innovatus* (5-10%), *Linnaea borealis* (5-10%), *Arctostaphylos uva-ursi* (6%), and *Calamagrostis rubescens* (2-10%). *Fragaria virginiana* and *Cornus canadensis* have low

cover but high frequency. The bryoid layer (25-60%) is dominated by *Pleurozium shcreberi* (10-25%) and *Peltigera aphthosa* (3-5%). Epiphytes are sparse with *Alectoria* spp. and *Letharia vulpina* most common.

EPIPHYTES										
Letharia vulpina	--	--	--	--	.5	--	.5	.5	.5	.5

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Stands of C9 are intermediate to advanced successionally with *Picea glauca* or *P. glauca* x *P. engelmannii* common in the tree layer and as regeneration in lower layers. Most stands are 85 to 100 years old.

The C9 v.t. is distinguished from C35 by occurring in Banff, by the presence and usual dominance of *Shepherdia canadensis* in the shrub layer, by the dominance of *Vaccinium caespitosum* rather than *Empetrum nigrum* in the herb-dwarf shrub layer, and by a lower ground lichen cover, usually <25%. Table 12 compares C9 with four other *Pinus contorta* v.t.s. The C9 differs by having *Vaccinium caespitosum* dominant in the herb-dwarf shrub layer rather than *Aster conspicuus* (C6), *Vaccinium scoparium* (C18) or *Linnaea borealis* (C19). The C3 differs in having greater amounts of *Juniperus communis* and *Arctostaphylos uva-ursi*.

Other Studies: Similar Alberta forests were described by Ogilvie (1963) in Banff (*Pinus contorta/Calamagrostis rubescens-Vaccinium*) and by Mackenzie-Grieve (1970) for the Red Deer River area east of Banff (*Pinus-Picea/Vaccinium caespitosum-Vaccinium vitis-idaea/Hylocomium* and *Pinus-Picea /Shepherdia-Vaccinium/Hylocomium*). Pfister et al. (1977) described similar forests for Montana as seral stages of the *Picea/Vaccinium caespitosum* and *Abies lasiocarpa/Vaccinium caespitosum* types as well as the somewhat drier *Pinus contorta/Vaccinium caespitosum* type.

C10: *Pinus contorta/Alnus crispa/Hylocomium splendens*

(lodgepole pine/green alder/feathermoss)

Environment: The C10 forests occur on mesic Montane to Lower Subalpine (1000-1780 m J; 1700 m B), level to steeply sloping sites of predominantly northerly aspect, primarily in Jasper. Soils are well drained Eutric and Dystric Brunisols developed on morainal landforms.

Vegetation: *Pinus contorta* is the dominant tree (Plate 13) with 10 to 55% cover (Table 18). *Picea glauca* has up to 20% cover and occurs in about one-half of the sampled stands. The shrub layer has moderate to high cover (15-55%), the dominant being *Alnus crispa* (10-50%) with lesser amounts of *Rosa acicularis* (<5%), *Shepherdia canadensis* (<10%), and *Viburnum edule* (<5%). *Menziesia glabella* (<3%) occurs in one-half of the sampled stands. The herb-dwarf shrub layer has moderate cover (10-40%) with common representatives being *Linnaea borealis* (<10%), *Cornus canadensis* (<10%), *Elymus innovatus* (3-15%), *Pyrola secunda* (<3%), *Pyrola asarifolia* (<3%), *Arnica cordifolia* (<5%), and *Aster conspicuus* (<10%). The bryoid layer has generally high cover (15-70%) and is dominated by *Hylocomium splendens* (15-75%) with lesser amounts of *Pleurozium schreberi* (5-45%), *Ptilium crista-castrensis* (<10%), and *Peltigera aphthosa* (<5%). *Parmelia sulcata* and *Cetraria pinastri* are common epiphytes.

Successionally, C10 is intermediate with most stands 70 to 100 years old.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

The C10 v.t. is distinguished from other *Pinus contorta* v.t.s by the dominance of *Alnus crispa* in the shrub layer. Stands with low *Alnus* cover may be transitional to C11, if cover of other species is low, or to C6 or C19 if *Shepherdia canadensis* has cover greater than that of *Alnus*. At higher elevations, intergrades to C14 occur with *Menziesia glabella* replacing *Alnus*.

Other Studies: In Alberta, similar types have been described by Ogilvie (1963, *Pinus/Hylocomium-Alnus*), La Roi (1975) in Jasper (*Pinus contorta/Alnus crispa* types), Corns and La Roi (1976) in the northern foothills, Corns (1978) also in the northern foothills (*Pinus contorta/Alnus crispa/Cornus canadensis*), and by La Roi and Hnatiuk (1980) in Banff and Jasper (*Pinus contorta/Alnus crispa/Linnaea borealis*). Mackenzie-Grieve (1970) described several similar types in the Red Deer River valley east of Banff (*Picea-Pinus/Hylocomium, Pinus-Picea/Alnus/Hylocomium, Pinus-Picea/Hylocomium, Pinus/Alnus/Aster, and Pinus-Populus/Alnus/Elymus*). Jacques and Legge (1974) have described a *Picea Alnus crispa-Aster conspicuus* type from the Kananaskis area to which C10 appears seral. In northeastern British Columbia, Raup (1934) described "rich pine woods" which have much *Alnus crispa* in the understory. Pfister et al. (1977), in Montana, have described similar *Pinus contorta* dominated, seral stands of the *Abies lasiocarpa/Alnus sinuata* type.

C11: *Pinus contorta-Picea* spp./*Hylocomium splendens*

(lodgepole pine/feathermoss)

Environment: The C11 v.t. occurs on mesic Montane to Lower Subalpine (1250-1750 m), gently sloping (<25%) sites with northerly aspects. Soils are well drained Eutric Brunisols on glacial landforms, occasionally with eolian or fluvial veneers.

Vegetation: *Pinus contorta* is the dominant tree (Plate 14) with 5 to 65% cover (Table 19). Usually lesser amounts of at least one of *Picea glauca* (<30%), *Picea engelmannii* (<30%), or *Picea mariana* (<25%) are also present in the tree layer which may have cover of up to 75%. The shrub layer is generally sparse (<15%) but where *Abies lasiocarpa* regeneration is abundant, may be as high as 35%. The most commonly occurring shrubs are *Shepherdia canadensis* (<5%), *Ledum groenlandicum* (<10%), and *Rosa acicularis* (<2%). The herb-dwarf shrub layer has cover generally <35%, with the majority in low-growing species such as *Linnaea borealis* (<25%) and *Cornus canadensis* (<5%). Other species commonly present are *Pyrola secunda* (<3%), *Elymus innovatus* (<5%), and *Arnica cordifolia* (<10%). The bryoid layer is well developed (60-100%), dominated by *Hylocomium splendens* (30-60%) and *Pleurozium schreberi* (10-50%) with lesser amounts of *Ptilium crista-castrensis* (5-10%). *Peltigera aphthosa* (5-15%) is the predominant terrestrial lichen, with much lesser

amounts of *Cladonia* spp. (<5%). Epiphytes have moderate abundance, the dominants being *Cetraria pinastri*, *Hypogymnia physodes*, and *Letharia vulpina*.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally C11 is intermediate to advanced and is probably seral to C13, with forests being 125 to 200 years old.

The C11 v.t. is distinguished from C13 by the dominance of *Pinus contorta*, from C20 by much less *Menziesia glabella* (<5%), from C19 by much less *Shepherdia canadensis* (<5%), and from C29 by low *Ledum groenlandicum* (<15%) and *Empetrum nigrum* (<2%) cover.

Other Studies: Similar types were described for Jasper and Banff by Laidlaw (1971, *Picea mariana-Hylocomium*) and for south central British Columbia by Illingworth and Arlidge (1960, *Pinus contorta/Cornus*-moss).

C12: ***Picea engelmannii-Pinus albicaulis/Menziesia glabella***

(Engelmann spruce-whitebark pine/false azalea)

Environment: The C12 v.t. occurs on mesic, mostly Lower Subalpine sites (1700-2100 m) on steep slopes of various aspects. The soils are well drained Eluviated Dystric Brunisols and Orthic Eutric Brunisols on morainal and colluvial landforms. C12 occurs mostly in the Main Ranges of Jasper and northern Banff, west of Highway 93 and between the North Saskatchewan and Miette Rivers.

Vegetation: The tree layer is closed (30-60%) and dominated by *Picea engelmannii* (10-20%), *Pinus albicaulis* (10-25%), and *Abies lasiocarpa* (5-20%) (Table 20). The moderately dense shrub layer (20-80%) is dominated by *Menziesia glabella* (20-75%). *Ledum groenlandicum* (5-10%) and *Abies lasiocarpa* (3-15%) are common. Often present, but with low cover, are *Rhododendron albiflorum*, *Pinus albicaulis*, and *Juniperus communis*. The herb-dwarf shrub layer, with a total cover of 10 to 70%, is dominated by dwarf shrubs: *Vaccinium scoparium* with very variable cover (5-60%), *Empetrum nigrum* (5-10%), *Vaccinium membranaceum* (1-5%), and *Vaccinium vitis-idaea* (<1%). The bryoid layer has a cover of 35 to 80% and is dominated by *Pleurozium schreberi* (20-35%). Other common species include *Dicranum scoparium* (5-10%), *Peltigera aphthosa* (1-2%), *Cladonia* spp. (1-5%), *Hylocomium splendens* (<1%), and *Barbilophozia* spp. (<1%). Epiphytes are moderately abundant with *Letharia vulpina*, *Parmeliopsis ambigua*, and *Parmeliopsis hyperopta* most common.

Stands of C12 are generally 200 to 300 years old and tree regeneration consists of *Picea engelmannii*, *Abies lasiocarpa*, and *Pinus albicaulis*. Thus, C12 is mature successionally.

The occurrence of *Pinus albicaulis* as a codominant tree in C12 differentiates it from C14.

Other Studies: Similar forests have been described in southwestern Alberta by Kuchar (1973) and Day (1967). Kuchar's (1978) whitebark pine forest in Yoho National Park, British Columbia includes stands similar to C12. Types lacking abundant *Menziesia glabella* and *Rhododendron albiflorum*, but otherwise similar, have been described from

Montana by Weaver and Dale (1974, *Pinus albicaulis-Vaccinium scoparium*) and Pfister et al. (1977, *Abies lasiocarpa-Pinus albicaulis/Vaccinium scoparium)* and central Wyoming by Reed (1976, *Pinus albicaulis-Vaccinium scoparium).*

C13: *Picea engelmannii-Abies lasiocarpa/Hylocomium splendens*

(Engelmann spruce-subalpine fir/feathermoss)

Environment: The C13 v.t. occurs on mesic to subhygric, predominantly Lower Subalpine (1250-2150 m J, 1390-2210 m B), level to steeply sloping sites on various aspects. Soils are well to moderately well drained Eutric and Dystric Brunisols and Regosols developed on glacial, colluvial, glaciofluvial and fluvial landforms.

Vegetation: *Picea engelmannii* is the dominant canopy tree (Plate 15) with 20 to 55% cover while *Abies lasiocarpa* usually has <15% cover (Table 21). Total tree cover is 25 to 60%. The shrub layer has low to moderate cover (10-40%) comprised primarily of regeneration of *Abies lasiocarpa* (5-15%) and *Picea engelmannii* (<10%). The herb-dwarf shrub layer has low cover (10-20%), characterized by *Pyrola secunda* (<3%), *Elymus innovatus* (<5%), *Linnaea borealis* (<10%), *Arnica cordifolia* (<5%), and *Equisetum scirpoides* (<5%). The bryoid layer has high cover (75-100%), dominated by *Hylocomium splendens* (30-75%) and *Pleurozium schreberi* (10-60%) with lesser amounts of *Ptilium crista-castrensis* (<15%), *Barbilophozia lycopodioides* (<5%), *Peltigera aphthosa* (<10%), and *Cladonia ecmocyna* (<1%). *Letharia vulpina* and *Parmeliopsis ambigua* are common epiphytes.

Succcessionally, C13 is mature with most stands 200 to 350 years old.

The C13 v.t. is distinguished from other similar v.t.s more by the absence rather than by presence or dominance of certain species. Some stands at the lower elevational limits of C13, where *Pseudotsuga menziesii* is present, are transitional to C5, or if *Pinus contorta* contributes significantly to the tree canopy, these stands are transitional to C11. Stands with *Menziesia glabella* cover approaching 20% or *Ledum groenlandicum* cover approaching 10% may be transitional to C14 or C30 respectively. High elevation stands with *Salix vestita* cover >5% or *Vaccinium scoparium* cover >15%, may be transitional to C24 or C15 respectively. The C13 v.t. is differentiated from C31 by having total cover of *Elymus innovatus* plus *Arnica cordifolia* plus *Linnaea borealis* <10% and *Elymus innovatus* cover <5%.

Other Studies: Similar forests are common from southern Yukon and Northwest Territories through northern and western Alberta and British Columbia. Orloci and Stanek (1979) described similar types *(Picea-HylocomiumPeltigera* and *Picea-Cornus-Hylocomium*) from southern Yukon; Jeffrey (1964) in the Mackenzie Mountains of southern Northwest Territories described similar mixed coniferous forest at high elevations. Farther south in west central Alberta foothills, similar vegetation was de-

scribed by Corns (1978, *Picea glauca/Hylocomium splendens*) and Lesko and Lindsay (1973, white spruce-feathermoss-alpine fir). In the Kananaskis area of Alberta, Kirby and Ogilvie (1969) described a similar type (*Picea-Abies/Hylomium-Cornus*) as did Jacques and Legge (1974, spruce-fir/*Cornus canadensis-Hylocomium splendens*) and Kondla (1978, spruce-fir/feathermoss and spruce/feathermoss types) also in the Kananaskis area. In Banff, forests described by Ogilvie (1976, *Picea-Abies/Hylocomium-Cornus*) are analogous and in Jasper, Hettinger's (1975) types (*Picea glauca/Linnaea borealis-Hylocomium splendens*, *Picea glauca/Carex vaginata-Linnaea borealis*, *Picea engelmannii-Abies lasiocarpa/Arnica cordifolia*, and *Picea engelmannii-Abies lasiocarpa/Arnica diversifolia*) are similar. In southern Alberta, climax coniferous vegetation described by Cormack (1953) is comparable, as is that described by Kuchar (1973) for Waterton Lakes National Park (spruce/fir/bunchberry). Similar types are also described from British Columbia by Kuchar (1978) in Yoho National Park (spruce-fir/five-leaved bramble, spruce-fir/bryophytes-lichens) and by Illingworth and Arlidge 1960) in south-central British Columbia (*picea glauca-Abies lasiocarpa/Cornus-moss).*

C14: ***Picea engelmannii-Abies lasiocarpa/Menziesia glabella/Vaccinium scoparium***

(Engelmann spruce-subalpine fir/false azalea)

Environment: The C14 forests occur on mesic to subhygric, Lower Subalpine (1360-1860 m J, 1500-2040 m B), level to steeply sloping sites of predominantly northerly aspect in western Jasper and Banff. The soils are well to moderately well drained Eutric and Dystric Brunisols, and Orthic Humo-Ferric Podzols developed primarily on glacial and colluvial landforms.

Vegetation: *Picea engelmannii* (15-75%) dominates the tree layer (Table 22, Plate 16). *Abies lasiocarpa* (5-15%) is usually present. Shrub cover is dense, (40-90%) dominated by *Menziesia glabella* (20-70%). *Ledum groenlandicum* (<10%) is present in about one-half of the sampled stands and *Rhododendron albiflorum* (<20%) may be abundant in high elevation stands. The herb-dwarf shrub layer is moderately well developed with 15 to 50% cover and is dominated by *Vaccinium scoparium* (5-40%) in most of Banff and Jasper but is replaced by *Vaccinium membranaceum* (5-15%) in northern Jasper. *Vaccinium myrtillus* (5-25%) occurs in about one-third of the stands. Other common species are *Cornus canadensis* (<5%), *Arnica cordifolia* (<10%), *Pyrola secunda* (<1%), *Lycopodium annotinum* (<5%), and *Linnaea borealis* (3-15%). The bryoid layer has high cover (70-90%) and is dominated by *Pleurozium schreberi* (25-60%), *Hylocomium splendens* (25-60%), and *Ptilium crista-castrensis* (5-15%). *Dicranum* spp. (<10%), *Barbilophozia lycopodioides* (5-20%), and *Barbilophozia hatcheri* are also important. Lichen cover is low (<10%), dominated by *Peltigera aphthosa* (<10%) and *Cladonia* spp., especially *Cladonia ecmocyna* (<2%).

Stands of C14 are successionally mature and are 100 to 300 years old.

The C14 v.t. is distinguished from C20, from which it succeeds, by having *Picea engelmannii* rather than *Pinus contorta*. The C14 is distinguished from C21 and other *Picea-Abies* types by abundant *Menziesia glabella*. Intergrades to C20 and C21 occur and stands with sparse *Menziesia* cover may be transitional to C13.

Other Studies: In Banff, Trottier and Scotter (1973) described similar types (*Picea-Abies/Menziesia glabella-Vaccinium scoparium*, *Picea-Abies /Menziesia glabella*/moss). In Jasper, similar types have been described by Hettinger (1975, *Picea engelmannii-Abies lasiocarpa/Menziesia glabella-Vaccinium membranaceum*), La Roi (1975, *Picea engelmannii/Abies lasiocarpa/Menziesia glabella/Valeriana sitchensis/Vaccinium scoparium/Pleurozium schreberi*), and Beil (1966). In other parts of Alberta, similar types have been described by Ogilvie (1976, Kirby and Ogilvie 1969, *Picea-Abies/Menziesia ferruginea -Lycopodium annotinum*), Kondla (1978) in Kananaskis Provincial Park (spruce-fir/false azalea-feathermoss), Kuchar (1973) in Waterton Lakes National Park (fir/spruce/menziesia), Jacques and Legge (1974) in the Kananaskis area (*Picea-Abies/Menziesia ferruginea-Tiarella unifoliata*, *Picea-Abies/Menziesia-Lycopodium annotinum*), and by Cormack (1953). In the northern foothills of Alberta, Corns (1978) has described a *Picea engelmannii-Abies lasiocarpa/Menziesia glabella* type similar to C14 stands in northern Jasper where *Vaccinium membranaceum* replaces *Vaccinium scoparium*. Shepherd (1959) has described a *Picea engelmannii-Abies/Peltigera* association in Banff, Kootenay and Yoho National Parks in Alberta and British Columbia. McLean (1970) described an *Abies lasiocarpa-Menziesia ferruginea* type from British Columbia. In Montana, Pfister et al. (1977) have described an *Abies lasiocarpa/Menziesia ferruginea* type. Daubenmire and Daubenmire (1968), in northern Idaho and eastern Washington, have a similar *Abies lasiocarpa-Menziesia ferruginea* type.

C15: *Picea engelmannii-Abies lasiocarpa/Vaccinium scoparium*

(Engelmann spruce-subalpine fir/grouseberry)

Environment: The C15 forests occur on mesic Upper Subalpine (1800-2140 m J; 1870-2240 m B), level to steeply sloping sites of predominantly southerly aspect in Banff and Jasper. Soils are well to moderately well drained Eutric and Dystric Brunisols, and Orthic Humo-Ferric Podzols developed primarily on morainal landforms.

Vegetation: *Picea engelmannii* (10-40%) is the dominant tree (Plate 17) while *Abies lasiocarpa* (<25%) is often codominant (Table 23). *Pinus contorta* and *Larix lyallii* occur occasionally. Tree cover is 20 to 60%. The shrub layer has variable cover (5-50%) and is dominated by *Abies lasiocarpa* (5-30%) and *Picea engelmannii* (<5%) regeneration. *Juniperus communis* (<5%) occurs in about one-half the sampled stands. The herb-dwarf shrub layer has moderate to high cover (25-85%) and is dominated by *Vaccinium scoparium* (15-60%) with lesser amounts of *Arnica cordifolia* (<10%), *Pedicularis bracteosa* (<10%), *Epilobium angustifolium* (<5%), and *Erigeron peregrinus* (<5%). *Phyllodoce* spp. and *Cassiope* spp., which are abundant in other Upper Subalpine v.t.s, are absent from many C15 stands or, where present, cover is usually <10%. Bryoid cover is generally high (40-85%) but is nearly absent in some stands. Moss cover varies from 5 to 85% dominated by *Pleurozium schreberi* (10-30%), *Barbilophozia lycopodioides* (5-20%), and *Barbilophozia hatcheri* (5-20%), with *Dicranum scoparium* (5-25%) often present. *Peltigera aphthosa* (<10%) is the dominant lichen and *Letharia vulpina* and *Alectoria* spp. are common epiphytes.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, C15 is mature with most stands 200 to 350 years old.

The C15 v.t. is distinguished from C34 and O10 by having low heath cover (<10%) and by high *Vaccinium scoparium* cover (15-60%). The C21 v.t. differs by having generally higher *Rhododendron albiflorum* and *Menziesia glabella* cover than C15 and by the dominance of *Vaccinium membranaceum* over *Vaccinium scoparium*. Stands transitional to C23 may occur where *Larix lyallii* has over one-half of the canopy cover or to C14 where *Menziesia glabella* cover approaches 20%.

Other Studies: Similar types occur from northern Jasper to Utah along the Rocky Mountains and westward to British Columbia and eastern Washington. In Alberta, similar types were described by La Roi (1975) for Jasper (*Abies lasiocarpa/Vaccinium scoparium/Barbilophosia lycopodioides*), for Banff by Ogilvie (1976, *Picea-Abies/Vaccinium scoparium/Phyllodoce* ssp.), Trottier and Scotter (1973, *Picea-Abies/Phyllodoce* ssp., *Picea-Abies/Vaccinium scoparium Picea-Abies/Vaccinium scoparium-Phyllodoce* ssp.-*Empetrum nigrum*), and for the Kananaskis area by Kirby and Ogilvie (1969, *Picea-Abies/Vaccinium scoparium*), Jacques and Legge (1974, spruce-fir/grouseberry), and Kondla (1978, spruce-fir/grouseberry). In British Columbia, similar types were described by McLean (1970) for the south-central part of the province (*Abies lasiocarpa-Vaccinium scoparium*), Kuchar (1978) for Yoho National Park (spruce-fir/grouseberry) and Kujala (1945) in central British Columbia (*Picea engelmannii-Abies lasiocarpa/Vaccinium scoparium*). Farther south, similar types have been described by Pfister et al. (1977) for Montana (*Abies lasiocarpa/Vaccinium scoparium*), by Bamberg and Major (1968) for the Flint Creek Mountains of west central Montana, by Patten (1963) for the Madison Range, southwestern Montana, and Daubenmire and Daubenmire (1968) for northern Idaho and eastern Washington (*Abies lasiocarpa-Vaccinium scoparium*). Similar types also occur in Wyoming, described by Reed (1976) for the Wind River Mountains (*Picea engelmannii-Vaccinium scoparium*), Despain (1973) for the Bighorn Mountains(*Picea engelmannii-Abies lasiocarpa*), Hoffman and Alexander (1976) for the Bighorn Mountains (*Picea engelmannii/Vaccinium scoparium, Abies lasiocarpa/Vaccinium scoparium*), Wirsing and Alexander (1975) for southeast Wyoming (*Abies lasiocarpa/Vaccinium scoparium*), and Oosting and Reed (1952) in the Medicine Bow Mountains. In Utah, Pfister (1972) has described an *Abies lasiocarpa/Vaccinium scoparium* type.

C16: *Populus tremuloides/Elymus innovatus-Lathyrus ochroleucus*

(aspen/hairy wild rye-peavine)

Environment: The C16 v.t. occurs on mesic, Montane to Lower Subalpine sites (1050-1550 m) on gentle slopes of southerly aspect in Banff and Jasper. The soils are well drained Orthic Eutric Brunisols and Regosols on fluvial landforms. A few stands in Jasper have Eutric Brunisols and Brunisolic Gray Luvisols developed on morainal landforms.

Vegetation: *Populus tremuloides* (20-60%) is dominant in the tree layer (Table 24, Plate 18). The shrub layer is moderately dense

(10-25%) with *Rosa acicularis* (5-10%), *Shepherdia canadensis* (5-15%), and *Juniperus communis* (<1%). The herb-dwarf shrub layer is dense (40-85%) and species rich with *Elymus innovatus* (15-40%) usually dominant. In Banff, *Calamagrostis rubescens* may be dominant to codominant. Other important species include: *Lathyrus ochroleucus* (1-3%), *Aster conspicuus* (<1%), and *Fragaria virginiana* (1-5%). Other species with low cover but high frequency are *Galium boreale*, *Vicia americana*, and *Achillea millefolium*. Lichens and bryophytes are scarce.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Stands of C16 are 60 to 120 years old and are intermediate to mature successionally. *Populus tremuloides* regeneration is common in many stands, while others have small amounts of *Picea glauca*, suggesting an increase in *Picea glauca* if the stand remains undisturbed.

The C16 v.t. differs from C22 in occurring on gentler slopes and on fluvial rather than colluvial landforms. *Lathyrus ochroleucus* and *Galium boreale* have higher cover in C16 than C22 and *Aster conspicuus*, while frequently present, has low cover in C16.

Other Studies: In Jasper, Hettinger (1975, *Populus tremuloides* type) and La Roi (1975, *Populus tremuloides* types) have described similar types. In both Banff and Jasper, Lulman (1976) described three *Populus tremuloides* dominated types which collectively constitute most of C16. In other parts of Alberta, similar types have been described by Jeffrey et al. (1968), Kondla (1978) in Kananaskis Provincial Park (aspen/hairy wild rye-bearberry), Kuchar (1973) in Waterton Lakes National Park (poplar forest), Ogilvie (1963, *Populus tremuloides* type), Mackenzie-Grieve (1970) for the Red Deer River valley east of Banff (*Populus/Elymus-Aster*), Ogilvie (1971) for the Porcupine Hills (aspen type), Moss (1955, aspen consociation of the *Populus* association) and, in the northern foothills by Corns (1978, *Populus tremuloides/Viburnum edule/Rubus pubescens*). In the Cypress Hills of Saskatchewan and Alberta, Newsome and Dix (1968) have described *Populus tremuloides* dominated forests which are similar to C16. Douglas (1974) has described a similar *Populus tremuloides/Arctostaphylos uva-ursi* type from the southwestern Yukon. In British Columbia, similar types have been described by Beil (1974, *Populus tremuloides/Rosa acicularis*), Kuchar (1978) in Yoho National Park (aspen-balsam poplar forest), and by Tisdale and McLean (1957, *Populus tremuloides/Calamagrostis*).

The C16 v.t. is also related to a group of types which extend south along the lower elevations of the Rocky Mountains in the United States. These include *Populus tremuloides/Symphoricarpos albus* in northwestern Montana (Lynch 1955), *P. tremuloides/Lupinus argenteus* in northern Wyoming (Hoffman and Alexander 1976), and *Populus tremuloides/Symphoricarpos oreophilus* in southern Wyoming (Reed 1971) and southern Colorado (Langenheim 1962, Morgan 1969).

C17: *Populus balsamifera/Shepherdia canadensis*

(balsam poplar/buffaloberry)

Environment: The C17 v.t. occurs on predominantly mesic Montane to Lower Subalpine (1000-1530 m), gently sloping (<25%) sites on various aspects. Soils are rapidly to moderately well drained Regosols developed on fluvial landforms.

Vegetation: *Populus balsamifera* (15-50%) is the dominant tree (Table 25, Plate 19). *Picea glauca* (<10%) occurs in many plots. The shrub layer has moderate to high cover

(20-80%), dominated by *Shepherdia canadensis* (10-70%), *Populus balsamifera* regeneration (<10%), *Rosa acicularis* (<5%), and *Cornus stolonifera* (<10%). The herb-dwarf shrub layer usually has moderate cover (25-60%) and is dominated by *Elymus innovatus* (10-30%) with lesser amounts of *Fragaria virginiana* (<3%), *Linnaea borealis* (<10%), *Aster ciliolatus* (<5%), and *Epilobium angustifolium* (<1%). The bryoid layer has low cover (<10%) with no high frequency of species. Epiphytes are sparse.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, C17 is early to intermediate. Abundant *Picea glauca* is often present, indicating possible succession to a *Picea glauca* dominated v.t., possibly C26.

The C17 v.t. is distinguished from C28 by occurring on drier sites with *Equisetum* spp. cover <5%.

Other Studies: The dry phase of the *Populus balsamifera* type described by Douglas (1974) in southwestern Yukon is similar, the major difference being the presence of *Lupinus arcticus* in the Yukon type. Kondla (1978) described a similar balsam poplar forest in Kananaskis Provincial Park, Alberta.

C18: *Pinus contorta/Shepherdia canadensis/ Vaccinium scoparium*

(lodgepole pine/buffaloberry/grouseberry)

Environment: The C18 v.t. occurs on mesic Lower Subalpine sites (1500-2020 m) on various slopes and all aspects. The soils are well drained Eutric Brunisols, less often Dystric Brunisols and Brunisolic Gray Luvisols, developed primarily on glacial landforms.

Vegetation: The tree layer is closed (25-55%) and dominated by *Pinus contorta* (25-50%) with *Picea* spp. (3-5%) often present (Table 26). *Shepherdia canadensis* (10-30%) dominates the moderately dense (15-40%) shrub layer (Plate 20). Also common is *Juniperus communis* (1-5%). The herb-dwarf shrub layer, with a total cover of 25 to 45%, is dominated by *Vaccinium scoparium* (20-45%). *Elymus innovatus* (5-25%), *Linnaea borealis* (3-10%), *Arnica cordifolia* (1-5%), *Cornus canadensis* (1-3%), and *Arctostaphylos uva-ursi* (1-2%) are common. *Pyrola secunda* and *Epilobium angustifolium* occur with high frequency but low cover. The bryoid layer has a cover of 30 to 65% and is dominated by *Pleurozium schreberi* (20-40%) and *Hylocomium splendens* (5-15%). *Dicranum* spp. (1-3%), *Peltigera aphthosa* (2-5%), and *Cladonia* spp. (1-2%) are also common. Epiphytes are scarce with *Letharia vulpina*, *Cetraria pinastri*, and *Alectoria* spp. most frequent.

Tree regeneration is predominantly *Picea* spp. Stands are mostly 60 to 100 years old and of fire origin. Thus, C18 is intermediate to advanced successionally. Further succession to C13 appears likely, although this is not clear.

The C18 v.t. is closely related to C6 and C19 and intergrading stands occur (Table 12). The C18 v.t. is distinguished from both by having *Vaccinium scoparium* dominant in the herb-dwarf shrub layer rather than *Aster conspicuus* (C6) or *Linnaea borealis* (C19). C18 often occurs at altitudes immediately above C19 and is distinguished from C15

by being dominated by *Pinus contorta* rather than *Picea engelmannii*.

Other Studies: Similar types have been described in Alberta by Kondla (1978) in Kananaskis Provincial Park (pine/grouseberry, pine/grouseberry-wild rye) and by Cormack (1953). In British Columbia, the *Pinus contorta/Vaccinium scoparium* and *Pinus contorta/Calamagrostis-Vaccinium scoparium* types of Illingworth and Arlidge (1960) are similar. Pfister et al. (1977) described similar *Pinus contorta* dominated, seral stages of the *Picea/Linnaea borealis* type where *Shepherdia canadensis* and *Vaccinium scoparium* are abundant. In northern Wyoming, *Pinus contorta* dominated, seral stands of the *Picea engelmannii/Vaccinium scoparium*, *Abies lasiocarpa/Vaccinium scoparium*, and *Abies lasiocarpa/Shepherdia canadensis* types (Hoffman and Alexander 1976) are similar to C18. The *Pinus contorta/Vaccinium scoparium* type (Hoffman and Alexander 1976) differs in having little or no *Shepherdia canadensis*. In southern Wyoming, Wirsing and Alexander (1975) described a similar *Pinus contorta/Vaccinium scoparium* type.

C19: *Pinus contorta/Shepherdia canadensis/Linnaea borealis*

(lodgepole pine/buffaloberry/twinflower)

Environment: The C19 v.t. occurs on mesic Montane to Lower Subalpine sites (1200-2000 m) on various slopes of southerly and westerly aspect. The soils are well drained Eutric Brunisols more often than Dystric Brunisols and Gray Luvisols. They are developed primarily on glacial landforms.

Vegetation: *Pinus contorta* (30-50%) dominates the closed tree layer (Table 27, Plate 21). *Picea* spp. occur frequently but with low cover, usually 1 to 10%. The moderately dense shrub layer (15-35%) is dominated by *Shepherdia canadensis* (10-30%). *Juniperus communis* (1-3%) and *Rosa acicularis* (<1-2%) are frequently present also. The herb-dwarf shrub layer has a total cover of 15 to 30% and is dominated by *Linnaea borealis* (10-25%) and *Elymus innovatus* (3-15%) or *Calamagrostis rubescens*. *Arnica cordifolia* (1-3%) and *Arctostaphylos uva-ursi* (1-3%) are often present, and *Aster conspicuus*, *Cornus canadensis*, *Pyrola secunda*, *Epilobium angustifolium*, and *Fragaria virginiana* occur with high frequency but low cover. The bryoid layer has a cover of 25 to 50% and is dominated by *Hylocomium splendens* (20-40%), *Pleurozium schreberi* (20-35%), and *Peltigera aphthosa* (1-3%). Epiphytes are generally scarce with *Letharia vulpina*, *Cetraria pinastri*, and *Alectoria* spp. most common.

Most C19 stands are 60 to 100 years old and are of fire origin. Tree regeneration is preponderantly *Picea* spp. and thus, C19 is intermediate to advanced successionally. Further successional development paths are not clear. However, succession to C31, C13 or C37 appears likely.

The C19 v.t. is closely related to C3, C6, and C18. Intergrading stands occur and Table 12 compares C19 and four other *Pinus contorta* v.t.s. C19 differs from the other v.t.s in having the herb-dwarf shrub layer dominated by *Linnaea borealis* rather than *Aster conspicuus* (C6), *Vaccinium scoparium* (C18), *Vaccinium caespitosum* (C9) or *Arctostaphylos uva-ursi* (C3). The C3 and C9 v.t.s also differ in having lower *Shepherdia canadensis* cover and C3 has higher *Juniperus communis* cover and *Pinus contorta* regeneration.

Other Studies: In Alberta, similar types have been described by Hettinger (1975) in northern Jasper (seral stage of *Pseudotsuga men-*

ziesii/Elymus) and by La Roi (1975, *Pinus contorta/Shepherdia canadensis/Rosa acicularis/Cornus canadensis/Linnaea borealis/Hylocomium splendens*, *Pinus contorta/Shepherdia canadensis/Lathyrus ochroleucus/Linnaea borealis/Pleurozium schreberi*, *Pinus contorta/Shepherdia canadensis/Elymus innovatus/Linnaea borealis/Peltigera canina*). In the Kananaskis area, Kondla (1978) described similar types: pine/twinflower, pine/buffaloberry-twinflower, and pine/buffaloberry-feathermoss. Cormack (1953) described similar vegetation from the southern Alberta foothills as seral to spruce-fir climax. Kuchar's (1978) types (lodgepole pine/buffaloberry/twinflower-bunchberry, lodgepole pine-spruce/buffaloberry/twinflower-bunchberry) from Yoho National Park bear strong similarity, while farther south, the seral stage of Pfister et al. (1977, *Picea/Linnaea borealis*) is very similar.

C20: *Pinus contorta/Menziesia glabella/Vaccinium scoparium*

(lodgepole pine/false azalea/grouseberry)

Environment: The C20 v.t. occurs on mesic Lower Subalpine (1400-1950 m J; 1550-2050 m B) level to steeply sloping sites with northerly and easterly aspects. Soils are well drained Eutric and Dystric Brunisols developed primarily on morainal and, to a lesser extent, on glaciofluvial landforms.

Vegetation: *Pinus contorta* (15-65%) is the dominant tree (Table 28). *Picea engelmannii* (<10%) and *Abies lasiocarpa* (<10%) are present in about one-half of the stands sampled with cover of <10% each. The shrub layer (Plate 22) is dense (30-70%) and is dominated by *Menziesia glabella* (10-70%), *Ledum groenlandicum* (<10%), and *Shepherdia canadensis* (<10%). *Rhododendron albiflorum*, (usually <10%) may occasionally achieve dominance to the exclusion of *Menziesia glabella*, particularly at higher elevations where precipitation is abundant. The herb-dwarf shrub layer usually has abundant cover (25-65%) and is dominated by *Vaccinium scoparium* (10-40%). *Vaccinium membranaceum* (10-35%) substitutes for *Vaccinium scoparium* in northern Jasper beyond the range of the latter. Other common representatives of this layer are *Linnaea borealis* (<10%), *Arnica cordifolia* (<15%), *Cornus canadensis* (<5%), *Elymus innovatus* (<5%), *Epilobium angustifolium* (<1%), and *Pyrola secunda* (<1%). The bryoid layer is well developed (30-90%) and dominated by *Pleurozium schreberi* (25-70%), *Hylocomium splendens* (10-40%), and *Ptilium crista-castrensis* (<10%). *Peltigera aphthosa* (<5%), *Barbilophozia lycopodioides* (<5%), and *Cladonia ecmocyna* (<5%) are also common. *Letharia vulpina* and *Alectoria* spp. are common epiphytes.

Successionally C20 is intermediate with most stands <150 years old.

The C20 v.t. is distinguished from C14 by having dominance of *Pinus contorta* rather than *Picea engelmannii* and from C18 by having dominance in the shrub layer of *Menziesia glabella* rather than *Shepherdia canadensis*. The C20 v.t. is normally seral to C14 but stands with abundant *Rhododendron albiflorum* and *Vaccinium membranaceum* may be seral to C21.

Other Studies: In Banff, Trottier and Scotter (1973) described a similar *Pinus contorta/Vaccinium scoparium* type and, in Jasper, La Roi (1975) has described a *Pinus contorta/Abies lasiocarpa/Menziesia glabella/Vaccinium scoparium/Pleurozium schreberi* type. In Banff and Jasper, La Roi and Hnatuik (1980) described a *Pinus contorta/Menziesia glabella/Vaccinium scoparium* type. Elsewhere

in Alberta, Ogilvie (1963, *Pinus contorta/ Menziesia ferruginea-Lycopodium annotinum*), Kondla (1978) in Kananaskis Provincial Park (pine/false azalea), and Corns (1978), in the northern foothills *(Pinus contorta/Menziesia glabella/Rubus pedatus)* have described similar types. In British Columbia, Kuchar (1978) described a lodgepole pine-spruce/menziesia/ grouseberry type from Yoho National Park.

C21: ***Picea engelmannii-Abies lasiocarpa/Vaccinium membranaceum/Barbilophozia lycopodioides***

(Engelmann spruce-subalpine fir/tall bilberry/ liverwort)

Environment: The C21 v.t. occurs on predominantly mesic Lower to Upper Subalpine (1650-2000 m J, 1750-2250 m B), gently to steeply sloping sites on various aspects in western Banff and Jasper. Soils are well drained Dystric and Eutric Brunisols, and Orthic Humo-Ferric Podzols developed on morainal and colluvial landforms.

Vegetation: *Picea engelmannii* (5-35%) is the dominant tree (Plate 23), while *Abies lasiocarpa* has generally <20% cover (Table 29). *Larix lyallii* occurs sporadically in some Banff stands. The shrub layer has low to high cover (5-70%), dependent largely upon the abundance of *Rhododendron albiflorum* (10-60%). *Abies lasiocarpa* (5-20%) regeneration is common in the shrub layer. The herb-dwarf shrub layer has moderate to high cover (20-70%) and is dominated by *Vaccinium membranaceum* (5-35%), *Vaccinium scoparium* (<15%), *Phyllodoce empetriformis* (<10%), *Empetrum nigrum* (<10%), and *Arnica cordifolia* (<5%). The bryoid layer generally has high cover (30-90%) and is dominated by *Pleurozium schreberi* (15-50%), *Barbilophozia lycopodioides* (5-40%), and *Dicranum scoparium* (<15%). *Peltigera aphthosa* (<5%) and *Cladonia ecmocyna* (<5%) are common. *Letharia vulpina* and *Parmeliopsis ambigua* are common epiphytes.

Successionally C21 is mature with many stands >300 years old.

The C21 v.t. is distinguished from C14 by abundant *Rhododendron albiflorum* and *Vaccinium membranaceum* rather than *Menziesia glabella* and *Vaccinium scoparium*, and C21 occurs at generally higher elevation. The C21 v.t. is distinguished from C15 by a shrub layer dominated by *Rhododendron albiflorum* and *Vaccinium membranaceum* instead of *Vaccinium scoparium*. Stands transitional to C14 and C15 occur. The C21 v.t. is distinguished from C24 by the usual absence of *Salix vestita* and *Cassiope tetragona*.

Other Studies: In Alberta, similar types have been desribed by Corns (1978) from the northern foothills (*Picea-engelmannii-Abies lasiocarpa/Menziesia glabella*), Beil (1966) for Jasper and Banff, Baig (1972) for Alberta Rockies (*Abies-Picea-Larix/Rhododenron*), and Trottier and Scotter (1973) for Banff (*Picea-Abies/Rododenron albiflorum-Vaccinium* ssp.). Kuchar (1978) described a similar spruce-fir/rhododendron type in Yoho National Park and similar vegetation occurs at

Logan Pass, Glacier National Park, Montana as reported by Habeck (1969).

C22: ***Populus tremuloides/Elymus innovatus-Aster conspicuus***

(aspen/hairy wild rye-showy aster)

Environment: The C22 v.t. occurs on mesic to subxeric, Montane to Lower Subalpine sites (1200-1800 m) on moderate to very steep (45-70%) slopes of southerly aspect in both Banff and Jasper. The soils are rapidly to well drained Orthic and Humic Regosols and Orthic Eutric Brunisols developed on colluvial and, to a minor extent, on fluvial and glacial landforms.

Vegetation: The tree layer (Plate 24) is dominated by *Populus tremuloides* (20-40%) (Table 30). The trees are often stunted, appearing more as tall shrubs than trees. Some stands are also quite open. The shrub layer is dense (20-50%) with *Populus tremuloides* (10-20%), *Rosa acicularis* (3-20%), and *Shepherdia canadensis* (1-2%). *Juniperus communis* is frequent but with cover <1%. The herb-dwarf shrub layer is also dense (60-80%). *Elymus innovatus* is dominant (20-50%) with lesser amounts of *Aster conspicuus* (5-10%) and *Arctostaphylos uva-ursi* (10-40%). *Fragaria virginiana, Achillea millefolium* , and *Hedysarum sulphurescens* (in Banff) occur with low cover and high frequency. The bryoid layer is very sparse with traces of *Tortula ruralis*. Epiphytes are nearly absent.

Letharia vulpina	--	--	--	--	--	--	--	.5	--

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Stands of C22 are 40 to 80 years old and

are intermediate successionally. Frequent disturbance due to colluviation and avalanching is important in maintaining this v.t.

The C22 v.t. differs from C16 in occurring on colluvial rather than fluvial landforms and on steeper slopes. The C22 v.t. generally has higher cover for *Aster conspicuus* and *Hedysarum sulphurescens* than C16, while *Lathyrus ochroleucus* and *Galium boreale* which are prominent in C16, are rare and infrequent in C22.

Other Studies: Baig (1972) has described a *Populus tremuloides/Elymus innovatus* type from Alberta which is similar to C22.

C23: *Larix lyallii-Abies lasiocarpa/Vaccinium scoparium-Antennaria lanata*

(subalpine larch-subalpine fir/grouseberry-everlasting)

Environment: The C23 v.t. occurs on mesic Upper Subalpine (2000-2450 m) gently to steeply sloping sites on various aspects in Banff south of a line running from Hector Lake to the Panther River. Soils are well to moderately well drained Dystric and Eutric Brunisols and Orthic Humo-Ferric Podzols on colluvial and morainal landforms.

Vegetation: *Larix lyallii* (10-60%) is the dominant tree (Plate 25) in this predominantly closed forest v.t. (Table 31). Open forests occur in more severe environments where they are often transitional to other types. *Abies lasiocarpa* (<20%) is also usually present in the tree layer. Shrub cover (15-40%) is primarily of *Abies lasiocarpa* and *Larix lyallii*. The herb-dwarf shrub layer usually has abundant cover (55-90%), the dominants being *Vaccinium scoparium* (5-40%), *Phyllodoce glanduliflora* (<25%), and *Antennaria lanata* (<10%). Other common species include *Erigeron peregrinus* (<5%), *Valeriana sitchensis* (<10%), *Arnica latifolia* (5-20%), *Cassiope mertensiana* (<20%), *Luzula wahlenbergii* (<5%), and *Pedicularis bracteosa* (<2%). The bryoid layer generally has low to moderate cover (<35%) dominated by *Barbilophozia* spp. and *Polytrichum juniperinum* (<5%). *Letharia vulpina* is a common epiphyte.

Successionally, C23 is mature with most stands 100 to 300 years old.

The C23 v.t. is distinguished from all other v.t.s by the dominance of *Larix lyallii*. Open forest stands with *Picea engelmannii* may be transitional to O10 or, where trees are very widely spaced, to L5. Closed forest stands with abundant *Picea engelmannii* may be transitional to C15 or to C21 where *Vaccinium membranaceum* is greater than *Vaccinium scoparium*.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

Other Studies: Similar types were described for Alberta by Baig (1972) for the southern Alberta Rocky Mountains (*Larix-Abies-Picea/Veronica americana; Larix-Abies/Luzula*), Jacques and Legge (1974) for the Kananaskis area of Alberta (spruce-fir-alpine larch grouseberry), Ogilvie (1976) for the Alberta Rockies (*Picea-Abies-Larix/Luzula wahlenbergii*), Trottier and Scotter (1973) for Banff (*Abies-Picea-Larix/Vaccinium scoparium/ Phyllodoce* spp.-*Cassiope mertensiana, Larix/Vaccinium scoparium/Trollius albiflorus/Carex nigricans, Abies-Picea-Larix/Phyllodoce* spp./*Vaccinium scoparium/Carex nigricans*), and Kuchar (1973) for Waterton Lakes National Park (fir/alpine larch). Elsewhere, Kuchar (1978)

described alpine larch forest in Yoho National Park, as did Pfister et al. (1977) for Montana (*Larix lyallii-Abies lasiocarpa*).Vegetation described by Arno and Habeck (1972) in the Pacific Northwest of the United States, especially western Montana and in southwestern Alberta appears very similar to the Banff *Larix* forests, although no types per se were recognized.

C24: ***Picea engelmannii-Abies lasiocarpa/Salix vestita/Cassiope tetragona***

(Engelmann spruce-subalpine fir/rock willow/ white mountain heather)

Environment: The C24 v.t. occurs on mesic to subhygric, mostly Upper Subalpine sites (1900-2200 m B, 1850-2100 m J) on moderate to steep slopes of northerly aspect in eastern Banff and Jasper. The soils are Static Cryosols and Eutric Brunisols developed on morainal and to a lesser extent on colluvial landforms. The landform surfaces are often soliflucted. Soil drainage varies from well to poorly drained with most soils moderately well to imperfectly drained.

Vegetation: The often sparse tree layer (15-40%) is dominated by *Picea engelmannii* (10-30%) and *Abies lasiocarpa* (3-10%) (Table 32, Plate 26). The shrub layer has a total cover of 15 to 45% and is dominated by *Salix vestita* (5-30%), *Abies lasiocarpa* (10-20%), and *Picea engelmannii* (1-5%). Herb-dwarf shrub layer cover (15-50%) varies greatly. *Cassiope tetragona* (10-35%), *Phyllodoce glanduliflora* (1-10%), and *Equisetum scirpoides* (2-15%) are dominant with *Pyrola secunda*, *Moneses uniflora*, and *Pedicularis bracteosa* frequently present but with low cover. The dense bryoid layer (30-80%) is dominated by *Hylocomium splendens* (10-50%), *Pleurozium schreberi* (5-30%), *Dicranum scoparium* (5-10%), *Drepanocladus uncinatus* (1-5%), *Barbilophozia lycopodioides* (1-5%), and *Peltigera aphthosa* (1-5%). Also present with low cover are *Cladonia gonecha*, *Peltigera canina*, *Nephroma expallidum*, and *Psoroma hypnorum*. Epiphytes are moderate with *Letharia vulpina*, *Hypogymnia austerodes*, *Cetraria pinastri*, and *Parmeliopsis ambigua* most common.

Stands of C24 are mostly 225 to 300 years old, have abundant *Picea engelmannii* and *Abies lasiocarpa* regeneration and are, thus, mature successionally.

The C24 v.t. is distingushed from C34 by having *Salix vestita* cover >5% and *Equisetum scirpoides* cover usually >2%. The O12 v.t. differs from C24 in generally being more open and having the herb-dwarf shrub layer dominated by *Arctostaphylos rubra* and *Dryas octopetala*. The O14 v.t. differs in being generally more open and having *Pedicularis bracteosa* dominant in the herb-dwarf shrub layer rather than *Cassiope tetragona* or *Phyllodoce glanduliflora*.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other Studies: No similar type has been described.

C26: ***Picea glauca/Shepherdia canadensis/ Thuidium abietinum***

(white spruce/buffaloberry/fern moss)

Environment: The C26 v.t. occurs on mesic, Montane to Lower Subalpine sites (1000-1600 m) of various slopes and usually northerly aspect in the east gate area of Jasper and the Saskatchewan Crossing area of Banff. The soils are generally well drained Cumulic Regosols on eolian and fluvial landforms.

C26 is restricted to areas where active deposition of calcareous loess is occurring.

Vegetation: *Picea glauca* (25-30%) is the dominant tree (Table 33). The shrub layer has a total cover >10%, often around 30%, and *Shepherdia canadensis* (>10%) is dominant (Plate 27). *Rosa acicularis* is often present but with cover <5%. *Juniperus communis* is also frequently present. The herb-dwarf shrub layer is dominated by *Elymus innovatus* (5-20%), *Linnaea borealis* (5-20%), and *Arctostaphylos uva-ursi* (3-15%). *Carex concinna* and *Pyrola secunda* occur with high frequency but with cover <3%. *Thuidium abietinum* (>50%) dominates the bryoid layer. *Peltigera aphthosa* and *Peltigera canina* occur with low cover, but species richness is low in this layer. Epiphytes are sparse to absent.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, C26 is mature with most stands 100 to 200 years old. Several stands which are 50 to 75 years old indicate that the C26 composition is established soon after fire.

The C27 v.t. differs from C26 by occurring only in Jasper and by having *Rosa acicularis* dominant in the shrub layer (Table 10). The C37 v.t. differs from C26 by having a bryoid layer dominated by *Hylocomium splendens* rather than *Thuidium abietinum*, although both types have a *Shepherdia canadensis* dominated shrub layer. The C2 v.t. has a shrub layer with <5% cover and a sparse herb-dwarf shrub layer, in contrast to the higher cover of these layers in C26.

Other Studies: Descriptions of similar types by other authors were not found.

C27: *Picea glauca/Rosa acicularis/Thuidium abietinum*

(white spruce/prickly rose/fern moss)

Environment: The C27 v.t. occurs on mesic, Montane sites (1000-1300 m) on nearly level to moderate slopes of northerly aspect mostly in the Athabasca River valley near the east gate of Jasper. The soils are Regosols on eolian and fluvial landforms. Deposition of calcareous loess is occurring on these sites.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The dominant tree is *Picea glauca*

(25-35%) (Table 34, Plate 28). The shrub layer has a total cover of 20 to 40% dominated by *Rosa acicularis* (10-20%). *Shepherdia canadensis* and *Lonicera dioica* occur frequently but with cover <5% usually. The herb-dwarf shrub layer has 30 to 40% cover and is dominated by *Elymus innovatus* (10-20%), *Linnaea borealis* (2-12%), and *Carex eburnea* (5-10%). *Geocaulon lividum*, *Zygadenus elegans*, *Smilacina stellata*, and *Fragaria virginiana* occur frequently but with low cover. *Thuidium abietinum* dominates the sparse bryoid layer. Terrestrial and epiphytic lichens are scarce to absent.

The C27 v.t. is mature successionally with most stands 120 to 150 years old.

The C27 v.t. differs from C26 by having the shrub layer dominated by *Rosa acicularis* rather than *Shepherdia canadensis*, and from C37 by the bryoid layer being dominated by *Thuidium abietinum* rather than *Hylocomium splendens* (Table 10). The C2 v.t. differs in having a shrub layer with <5% cover and a sparse herb-dwarf shrub layer.

Other Studies: The "upland white spruce forest" type of Kuchar (1972) in Jasper is similar to C27.

C28: *Populus balsamifera/Equisetum pratense*

(balsam poplar/horsetail)

Environment: The C28 v.t. occurs on hygric to subhygric, Montane (1000-1100 m) sites of gentle slope (<5%) on various aspects in Jasper. The soils are imperfectly to well drained Regosols developed on fluvial landforms in broad valleys where wetter soils are prevalent.

Vegetation: *Populus balsamifera* is the dominant canopy tree with 35 to 55% cover and *Picea glauca* may be present in small amounts (Table 35). Shrub cover is low (<15%) with *Rosa acicularis* (2%) and *Viburnum edule* (<5%) predominating. The herb-dwarf shrub layer has high cover (55-80%) and is dominated by *Equisetum pratense* (<60%), *Equisetum arvense* (<20%), and *Mertensia paniculata* (<15%). Other characteristic species include *Rubus pubescens* (<5%), *Petasites palmatus* (<2%), *Vicia americana* (1%), and *Galium triflorum* (<1%). The bryoid layer has very low coverage (1%) with traces of *Brachythecium salebrosum*, *Bryum caespiticium*, and *Mnium cuspidatum*. Successionally, C28 is intermediate with trees less than 100 years, and eventual succession to C32 appears likely when the site becomes geomorphically stable and is no longer susceptable to periodic flooding.

The C28 v.t. is distinguished from C16 by the dominance of *Populus balsamifera* rather than *Populus tremuloides* and by wetter soils on more gentle slopes. The C17 v.t. occurs on drier (mesic) sites, and has *Shepherdia canadensis* as the dominant shrub and a low cover, if any, of *Equisetum* spp..

C29: *Pinus contorta/Ledum groenlandicum*

(lodgepole pine/Labrador tea)

Environment: The C29 v.t. occurs on mesic, Montane to Lower Subalpine sites (1400-1850

m) on various slopes of northerly aspect. The soils are well drained Eutric Brunisols, Brunisolic Gray Luvisols, and Dystric Brunisols on eolian, morainal, and fluvial landforms.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: *Pinus contorta* (20-45%) dominates the closed tree layer (Plate 29), with *Picea engelmannii* or *Picea engelmannii* x *Picea glauca* common (≤10%) (Table 36). The shrub layer has a total cover of 25 to 50% with *Ledum groenlandicum* (10-40%) dominant. *Shepherdia canadensis* (1-5%), *Salix glauca* (1-5%), and *Juniperus communis* (1-3%) are often also present. The herb-dwarf shrub layer has moderate to dense cover (25-50%) and commonly contains *Vaccinium scoparium* (5-15%), *Linnaea borealis* (3-5%), *Vaccinium vitis-idaea* (3-5%), *Elymus innovatus* (1-5%), *Arnica cordifolia* (1-5%), and *Cornus canadensis* (1-5%). The dense bryoid layer (40-80%) is dominated by *Pleurozium schreberi* (35-45%), *Hylocomium splendens* (20-35%), *Ptilium crista-castrensis* (5-15%), and *Peltigera aphthosa* (1-3%). Common epiphytes include *Letharia vulpina*, *Cetraria pinastri*, *Usnea sorediifera*, and *Parmeliopsis ambigua*.

The C29 v.t. is intermediate to advanced successionally with most stands 75 to 200 years old. The presence of *Picea engelmannii* and *Abies lasiocarpa* in lower layers indicates succession to C30 as a mature stage.

The C29 v.t. is distinguished from C30 by having *Pinus contorta* dominant in the tree layer rather than *Picea engelmannii*.

Other Studies: Similar types have been described in Alberta by Ogilvie (1976, seral *Pinus contorta* dominated stands of the *Picea-Abies/Ledum-Empetrum* type), La Roi (1975) in Jasper (*Pinus contorta/Ledum groenlandicum/Vaccinium scoparium/Linnaea borealis/Hylocomium splendens*), by Corns (1978) in the northern foothills of Alberta (*Pinus contorta/Ledum groenlandicum/Pleurozium schreberi*), and by La Roi and Hnatiuk (1980) in Banff and Jasper (*Pinus contorta/Ledum groenlandicum/Vaccinium scoparium*).

C30: *Picea engelmannii-Abies lasiocarpa/Ledum groenlandicum/Empetrum nigrum*

(Engelmann spruce-subalpine fir/Labrador tea/crowberry)

Environment: The C30 v.t. occurs on mesic, Lower Subalpine sites (1540-2000 m) on gentle to moderate slopes of usually northerly and easterly aspect. The soils are well drained Eutric and Dystric Brunisols on eolian and morainal landforms.

Vegetation: The closed tree layer (Plate 30) is dominated by *Picea engelmannii* (20-40%) with lesser amounts of *Abies lasiocarpa* (5-10%) and *Pinus contorta* (<5%) (Table 37). The shrub layer has moderately dense cover (30-50%) and is dominated by *Ledum groenlandicum* (10-30%), with *Abies lasiocarpa* (3-10%), *Picea engelmannii* (3-5%), and *Salix glauca* (1-3%). *Empetrum nigrum* (8-20%) dominates the herb-dwarf shrub layer. Other common species are: *Vaccinium vitis-idaea* (3-5%), *Elymus innovatus* (5%), *Vaccinium scoparium* (5-10%), *Arnica cordifolia* (1-3%), and *Cornus canadensis* (1-3%). The dense bryoid layer (50-80%) contains *Hylocomium splendens* (30-50%), *Pleurozium schreberi* (15-35%), *Ptilium crista-castrensis* (5-15%), and *Peltigera aphthosa* (1-3%). Common epiphytes include *Letharia vulpina*, *Cetraria pinastri*, and *Parmeliopsis ambigua*.

The C30 v.t. is mature successionally with stands typically 200 to 400 years old. *Picea engelmannii* and *Abies lasiocarpa* regeneration is common in the lower layers.

The C30 v.t. is distinguished from C29 by having dominance of *Picea engelmannii* in the tree layer and the usual dominance of *Empetrum nigrum* in the herb-dwarf shrub layer.

Other Studies: Similar types were described for Alberta by La Roi (1975) for Jasper (*Picea engelmannii/Abies lasiocarpa/Ledum groenlandicum/Vaccinium scoparium/Hylocomium splendens*), Ogilvie (1963) for Banff (*Picea-Abies/Ledum groenlandicum*), and Trottier and Scotter (1973) for Banff (*Picea-Abies/Ledum groenlandicum-Empetrum nigrum*).

C31: *Picea engelmannii-Abies lasiocarpa/Elymus innovatus-Arnica cordifolia-Linnaea borealis/Hylocomium splendens*

(Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss)

Environment: The C31 v.t. occurs on mesic, Lower Subalpine (1700-1975 m) sites of moderate slope on various aspects, mostly in the Front Ranges of eastern Banff and Jasper. The soils are generally well drained Eutric Brunisols developed on fluvial and glacial landforms.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: *Picea engelmannii* is the dominant canopy tree (Plate 31) with 30 to 45% cover (Table 38). *Abies lasiocarpa* is usually present but with much lower cover (1-5%). *Pinus contorta* may also be present (<5%). The shrub layer has <5% cover with *She-*

pherdia canadensis and *Juniperus communis* as common dominants. Herb-dwarf shrub layer cover is >15%. Dominant species are *Elymus innovatus* (5-10%), *Linnaea borealis* (5-15%), and *Arnica cordifolia* (5-10%). *Vaccinium scoparium* is often present with 5 to 15% cover. The bryoid layer is dominated by *Hylocomium splendens* (20-50%) and *Pleurozium schreberi* (20-30%) and has a total cover of 40 to 75%. *Peltigera aphthosa* is nearly always present with <10% cover. Epiphytic lichens are in moderate abundance with *Usnea sorediifera* and *Alectoria glabra* most common.

Successionally, C31 is predominantly mature with most stands 200 to 300 years old. Earlier successional stages are similar to C19.

The C31 v.t. is distinguished from C13 by having a herb-dwarf shrub cover >15% and a total cover of *Elymus innovatus* plus *Arnica cordifolia* plus *Linnaea borealis* >10%. *Vaccinium scoparium* is often present in C31 with >5% cover while in C13 it is usually absent. The C33 v.t. differs from C31 in having <25% cover of feathermosses (*Hylocomium splendens, Pleurozium schreberi, Ptilium crista-castrensis*) and by occurrences usually at elevations >2000 m. Intergrades to C13 and C33 occur.

Other Studies: In Banff, Trottier and Scotter (1973) have described a *Picea-Abies/Shepherdia canadensis* type which is similar to C31. In Jasper, Hettinger (1975) has described a similar *Picea glauca/Elymus innovatus-Cornus canadensis* type, while in the Porcupine Hills, Duffy (1971) and Ogilvie (1971) have described similar herb-rich white spruce forests. Pfister et al. (1977) have described a similar *Abies lasiocarpa/Arnica cordifolia* type in Montana.

C32: *Picea engelmannii/Equisetum arvense/Hylocomium splendens*

(Engelmann spruce/horsetail/feathermoss)

Environment: The C32 v.t. occurs on mesic to subhygric sites mostly in the Lower Subalpine (usually <1500 m in Jasper; 1460-1870 m in Banff) on gentle to moderate slopes on various aspects in eastern Banff and Jasper. The soils are Regosols and Rego Gleysols on fluvial landforms.

Vegetation: *Picea engelmannii* (with *P. engelmannii* x *P. glauca* hybrids at lower elevations) is the dominant canopy tree with 20 to 40% cover (Table 39). The shrub layer is generally sparse with <15% cover contributed mostly by tree regeneration. Herb-dwarf shrub cover is 35 to 70% with *Equisetum arvense* (20-50%) dominant (Plate 32). Also common are *Arnica cordifolia* (3-5%), *Elymus innovatus* (<5%), *Linnaea borealis* (5%), *Mertensia paniculata* (≤1%), and *Mitella nuda* (≤1%). Bryoid cover is 50 to 80%, *Hylocomium splendens* (25-50%) is dominant, followed by *Pleurozium schreberi* (10%), *Ptilium crista-castrensis* (5%), and *Peltigera aphthosa* (3%).

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, C32 is mature with stand ages of 200 to 400 years. *Picea engelmannii* regeneration is common in the shrub layer.

The C32 v.t. is similar to C4 but generally occurs on drier, Lower Subalpine (>1500 m) sites with a sparse shrub layer in which *Rosa acicularis, Cornus stolonifera,* and *Alnus tenuifolia* are usually absent, and with *Arnica cordifolia, Elymus innovatus,* and *Mertensia paniculata* in the herb-dwarf shrub layer.

Other Studies: Similar types have been described for Alberta by Corns (1978) for the northwestern foothills (*Picea glauca/Equisetum arvense/Hylocomium splendens*), Mackenzie-Grieve (1970) for the Red Deer

River area east of Banff (*Populus-Pinus/Heracleum-Delphinium-Aster-Equisetum*), Kirby and Ogilvie (1969, *Picea-Abies/Equisetum*), and Jacques and Legge (1974, spruce-fir/horsetail) for the Kananaskis area of Alberta. Trottier and Scotter (1973) described a similar type (*Picea-Abies/Equisetum*) for Banff and Cormack (1953) described similar vegetation for southwestern Alberta as part of his climax spruce-fir forest complex.

C33: *Picea engelmannii/Elymus innovatus*

(Engelmann spruce/hairy wild rye)

Environment: The C33 v.t. occurs on predominantly mesic to subxeric Upper Subalpine (1700-2240m), gently to steeply sloping sites with southerly aspect in eastern Banff. Soils are well drained Eutric Brunisols and Regosols developed on morainal and colluvial landforms.

Vegetation: *Picea engelmannii* (15-50%) is the dominant tree (Table 40, Plate 33). *Pinus contorta* (<10%) occurs in many plots. *Abies lasiocarpa* is usually absent. The shrub layer has low to moderate cover (5-35%) dominated by *Picea engelmannii* regeneration (5-15%), *Juniperus communis* (<5%), and *Shepherdia canadensis* (<5%). The herb-dwarf shrub layer has moderate to high cover (20-85%) and is dominated by *Elymus innovatus* (5-40%). Other characteristic species include *Arctostaphylos uva-ursi* (<10%), *Linnuea borealis* (1-10%), *Hedysarum sulphurescens* (<10%), *Arnica cordifolia* (2-10%), *Fragaria virginiana* (<5%), and *Zygadenus elegans* (<5%). The bryoid layer has generally low cover (<30%) with *Hylocomium splendens* (<15%) and *Pleurozium schreberi* (<10%) accounting for most of the cover. *Peltigera aphthosa* (<10%) and *Cladonia* spp. (<5%) are also present. *Letharia vulpina* is common as an epiphyte.

Successionally C33 is mature with stands 100 to 350 years old.

The C33 v.t. is distinguished from C31 by occurring at higher elevations, having <25% feathermoss cover and by generally drier sites.

Other Studies: No similar type has been described by other workers.

C34: *Picea engelmannii-Abies lasiocarpa/Phyllodoce glanduliflora/Hylocomium splendens*

(Engelmann spruce-subalpine fir/heather/feathermoss)

Environment: The C34 v.t. occurs on mesic Upper Subalpine sites (1900-2200 m) on moderate to steep slopes of northerly and easterly aspect. The soils are well to moderately well drained Eutric and Dystric Brunisols and Orthic Humo-Ferric Podzols on morainal landforms.

Vegetation: The tree layer is closed (20-40%) and dominated by *Picea engelmannii* (15-30%) and *Abies lasiocarpa* (5-25%) (Table 41). The shrub layer is moderately dense (10-30%) and composed almost entirely of *Abies lasiocarpa* (10-25%) and *Picea engelmannii* (1-5%) regeneration. The herb-dwarf shrub layer is dense (30-65%) and dominated by *Phyllodoce*

glanduliflora (10-50%) or occasionally *Phyllodoce empetriformis* (Plate 34). Other important dwarf shrubs are *Vaccinium scoparium* (5-15%) and *Cassiope mertensiana* (5-10% in Jasper) or *Cassiope tetragona* (3-5% in Banff). Herb cover is very low. The bryoid layer has a total cover of 40 to 90% and is dominated by *Hylocomium splendens* (10-40%) and *Pleurozium schreberi* (15-45%). Other important species are *Dicranum scoparium* (5-20%), *Drepanocladus uncinatus* (5-10%), *Barbilophozia lycopodioides* (1-5%), *Peltigera aphthosa* (1-5%), and *Cladonia ecmocyna* (1-3%). Epiphytes are in moderate abundance with *Letharia vulpina*, *Parmeliopsis ambigua*, *Parmeliopsis hyperopta*, *Bryoria fremontii*, and *Bryoria glabra* most common.

The C34 v.t. stands are 200 to 400 years old and are mature successionally.

The C34 v.t. is distinguished from O10 by having a closed physiognomy and by slightly lower elevations, from C13 by greater cover of *Phyllodoce* spp., *Cassiope* spp., and *Vaccinium scoparium* and usually lower elevations, from C24 by *Salix vestita* cover <5% and *Equisetum scirpoides* cover <2%, and from C15 by the dominance of *Phyllodoce* spp. rather than *Vaccinium scoparium*.

Other Studies: Descriptions of similar types by other authors were not found.

C35: *Pinus contorta-(Picea engelmannii)/Empetrum nigrum/ Cladonia mitis*

(lodgepole pine-(Engelmann spruce)/crowberry/ lichen)

Environment: The C35 v.t. occurs on subxeric Lower Subalpine sites (1600-1850 m) on nearly level to moderate slopes on various aspects in northern Jasper. The soils are rapidly drained Eluviated Dystric Brunisols on noncalcareous glaciofluvial and ice contact stratified genetic materials.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The tree layer is generally closed (25-40%), although some stands are more open with <20% cover (Table 42). *Pinus contorta* (25-35%) is usually dominant (Plate 35), often with lesser amounts of *Picea engelmannii* (5-8%), but occasionally *Picea engelmannii* is codominant. The shrub layer is

sparse (≤15%) and composed mostly of tree regeneration. The herb-dwarf shrub layer has 30 to 50% cover and is dominated by dwarf shrubs: *Empetrum nigrum* (15-35%), *Vaccinium vitis-idaea* (3%), *Vaccinium caespitosum* (4%). *Juniperus communis* occurs with high frequency but low cover. The bryoid layer is generally dense (40-65%) and dominated by lichens. Lichen cover is usually ≥25% and consists of *Cladonia mitis* (10-15%), *Stereocaulon tomentosum* (3-5%), *Peltigera aphthosa* (<1%), and various *Cladonia* spp. (3-10%), especially *C. uncialis, C gonecha,* and *C. cornuta. Letharia vulpina* is a common epiphyte.

Most stands are 175 to 250 years old and contain both *Pinus contorta* and *Picea engelmannii* regeneration. Thus, C35 appears stable on these dry sites and is advanced to mature successionally.

The C35 v.t. is distinguished from C9 by occurring in northern Jasper rather than Banff, by the usual absence of *Shepherdia canadensis*, by *Empetrum nigrum* dominance and lower *Vaccinium caespitosum* cover in the herb-dwarf shrub layer, and by a higher ground lichen cover, typically ≥25%.

Other Studies: Jeffrey (1964) described a related lodgepole pine-lichen woodland from the southwestern Northwest Territories.

C36: *Pinus contorta-Picea glauca/Salix glauca/ Elymus innovatus*

(lodgepole pine-white spruce/willow/hairy wild rye)

Environment: The C36 v.t. occurs on mesic to subhygric Lower Subalpine sites (1400-1700 m J, to 1900 m B) on gentle to moderate slopes on various aspects, primarily in the north end of Jasper. The soils are well drained Eutric Brunisols on fluvial landforms.

Vegetation: *Pinus contorta* is the dominant canopy tree with 10 to 25% cover (Table 43). *Picea glauca* is often present to co-dominant. The shrub layer, with a total cover of 25 to 45%, is dominated by *Salix glauca* (15-30%) with lesser amounts of *Betula glandulosa* (5-10%), *Shepherdia canadensis* (<5%), and *Ledum groenlandicum* (5%). Herb-dwarf shrub cover is 35 to 65% with *Elymus innovatus* (10-25%), *Linnaea borealis* (5%), *Epilobium angustifolium* (≤3%), and *Fragaria virginiana* (2-3%). The bryoid layer has a cover of 20 to 50% with *Hylocomium splendens, Pleurozium schreberi, Peltigera aphthosa,* and *Cladonia* spp. Epiphytes are scarce.

The C36 v.t. is intermediate successionally with stands generally 50 to 70 years old. Stands often show evidence of repeated burns at short intervals and *Picea glauca* is frequently present as remnants or snags.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

The C36 v.t. differs from C37 in having *Salix glauca* as the dominant shrub rather than *Shepherdia canadensis* and in being at an intermediate, rather than mature, successional stage. The C37 v.t. also occurs in the Montane as well as Lower Subalpine. The C36 v.t. also has some similarities to O18, but the latter is open forest, occurs in both Lower and Upper Subalpine, and has many different species in the herb-dwarf shrub layer despite similar dominance by *Elymus innovatus.*

Other Studies: Descriptions of similar types by other authors were not found.

C37: *Picea glauca/Shepherdia canadensis/Hylocomium splendens*

(white spruce/buffaloberry/feathermoss)

Environment: The C37 v.t. occurs on mesic Montane to Lower Subalpine (1000-1800 m) sites on various slopes and predominantly

northerly aspect in both Banff and Jasper. The soils are well drained Regosols and Eutric Brunisols on fluvial and morainal landforms. Deposition of calcareous loess appears to be less on these sites than in C2, C26 and C27.

Vegetation: *Picea glauca* (20-50%) is the dominant tree (Table 44). In Lower Subalpine stands, the *Picea* is frequently a *Picea glauca x P. engelmannii* hybrid. *Pinus contorta* occurs frequently with cover <10%. The shrub layer has a total cover of 10 to 60% and is dominated by *Shepherdia canadensis* (10-50%). *Juniperus communis, Salix glauca*, and *Rosa acicularis* occur with high frequency but with cover generally <10%. The herb-dwarf shrub layer has 20 to 50% cover and is dominated by *Elymus innovatus* (1-35%), *Linnaea borealis* (1-20%), and *Arctostaphylos uva-ursi* (<5%). Other species with high frequency but low cover are *Pyrola secunda, Fragaria virginiana, and Equisetum scirpoides*. The bryoid layer is well developed with a total cover of 40 to 80%. Generally, *Hylocomium splendens* is dominant (20-70%) with lesser amounts of *Pleurozium schreberi* (5-15%), *Ptilium crista-castrensis* (<5%), and *Peltigera aphthosa* (<5%). *Drepanocladus uncinatus* and *Thuidium abietinum* are often present but have low cover. Epiphytes are scarce.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The C37 v.t. is mature successionally with most stands 125 to 300 years old. C37 appears to develop, following fire, often from *Pinus contorta* forest (C19, C6), but some C37 stands less than 100 years old contain little *P. contorta* and it appears that sometimes *Picea glauca* occupies the site immediately after fire rather than *P. contorta*.

The C37 v.t. differs from C26 (Table 10) by having *Hylocomium splendens* as the dominant bryoid rather than *Thuidium abietinum*, from C27 by having *Shepherdia canadensis* the dominant shrub and *Hylocomium splendens* the dominant bryoid rather than *Rosa acicularis* and *Thuidium abietinum*, and from C2 by having well-developed shrub and herb-dwarf shrub layers and *Hylocomium splendens* the dominant bryoid.

Other Studies: Similar types have been described by La Roi (1967, part of white spruce-fir), Douglas (1974) in the southwest Yukon (*Picea glauca/Shepherdia canadensis*), and Kondla (1978) in Kananaskis Provincial Park (spruce-fir/buffaloberry-grouseberry).

O2: *Pinus flexilis-Pseudotsuga menziesii/Juniperus* spp./*Arctostaphylos uva-ursi*

(limber pine-Douglas fir juniper/bearberry)

Environment: The O2 limber pine forest occurs on xeric to subxeric Montane (1340-1420 m), moderate to steeply sloping south facing erosional scarps along the lower Bow and North Saskatchewan Rivers in Banff. These sites are among the warmest and driest in the parks. Soils are rapidly drained Orthic Regosols developed on eroded glacial landforms.

Vegetation: *Pinus flexilis* is the predominant canopy tree or may be present only as a tall shrub (Plate 36). Total cover is 5 to 40%, creating a closed forest variant in some stands (Table 45). *Pseudotsuga menziesii* has 10 to 15% cover while *Picea glauca* has <5%. Shrub cover is high (30-50%) dominated by *Juniperus scopulorum* (15-20%) and *Juniperus communis* (5-10%), with a small amount of *Potentilla fruticosa* (<2%). *Juniperus scopulorum* is absent from the stands at Saskatchewan Crossing. Herb-dwarf shrub cover is moderate to high (30-55%) dominated by *Arctostaphylos uva-ursi* (20%) with other characteristic species being *Artemisia frigida* (<5%), *Erigeron caespitosus* (<4%), *Anemone patens* (<3%), *Oxytropis sericea* (<2%), *Carex filifolia* (<1%), and *Senecio canus* (<1%). Bryoid cover is low (<2%).

The O2 v.t. is successionally mature with stands 150 to 300 years old.

The O2 v.t. is distinguished from all other v.t.s by the presence of *Pinus flexilis* and abundant *Juniperus scopulorum*. It is most similar to O5 in which *Pinus flexilis* is absent.

Other Studies: In Alberta, similar types were described by Kuchar (1973) for Waterton Lakes National Park (limber pine-scrub) and for the Porcupine Hills by Duffy (1971). In British Columbia, Kuchar (1978) described a similar type for Yoho National Park and in southern British Columbia, Brayshaw (1970) described a *Pseudotsuga menziesii-Pinus ponderosa-Arctostaphylos uva-ursi* type that is similar except that *Pinus ponderosa* appears to substitute for *Pinus flexilis*. In Montana, the *Pinus flexilis/Juniperus communis* type and *Juniperus* woodlands described by Pfister et al. (1977) are also similar.

O3: *Picea glauca/Potentilla fruticosa/Arctostaphylos uva-ursi*

(white spruce/shrubby cinquefoil/bearberry)

Environment: The O3 v.t. occurs predominantly on subxeric to mesic Montane (1000-1500 m), level to gently sloping sites of various aspect. A few stands occur above 1500 m in the Lower Subalpine. The soils are rapidly to well drained Regosols on fluvial landforms. The ground water regime can vary greatly within a stand depending on stand microtopography and seasonal variation in the depth to water table. Thus, several O3 stands have a subhygric moisture regime with imperfectly to poorly drained soils showing gley features.

Vegetation: *Picea glauca* (5-20%) is predominant in the open tree layer (Table 46 , Plate 37). A few stands with a closed tree layer are also included here as a closed variant. In Lower Subalpine stands, *Picea engelmannii* occasionally replaces *Picea glauca*. The shrub layer has a total cover of 10 to 40% and is dominated by *Potentilla fruticosa* (1-15%), *Shepherdia canadensis* (1-10%), and *Juniperus communis* (<10%). The herb-dwarf shrub layer has a total cover of 20 to 60%. Dominant species are *Arctostaphylos uva-ursi* (5-35%), *Elymus innovatus* (1-30%), and *Fragaria virginiana* (1-3%). The bryoid layer has a low cover (<30%) with the predominant species being *Thuidium abietinum* (1-10%), *Ditrichum flexicaule* (<3%), and *Peltigera canina* (<1%). Epiphytes are scarce.

The O3 v.t. is intermediate to mature successionally with stands 80 to 250 years old.

The O3 v.t. is closely related to O17 and intergrading stands occur. O3 is distinguished by: *Potentilla fruticosa* cover usually > 1% altitude usually <1500 m (Montane), landform usually fluvial, and soil usually Regosolic. In contrast, *Potentilla fruticosa* is typically absent in O17 or has <1% cover, the altitude is >1500 m (Lower Subalpine), the landform is colluvial or morainal, and the soil is Brunisolic or, if the landform is colluvial, the soil may be Regosolic.

Tortula ruralis	--	--	--	--	--	--	--	--	.5	01	.5

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other Studies: Similar types have been described from Jasper by Laidlaw (1971, *Picea mariana-Potentilla*) and La Roi (1975, *Picea glauca/Potentilla fruticosa/Arctostaphylos uva-ursi/Thuidium abietinum, Picea glauca/Elaeagnus commutata/Potentilla fruticosa/Arctostaphylos uva-ursi*).

O4: *Picea engelmannii-Abies lasiocarpa-Pinus albicaulis-Pinus contorta*

(Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine)

Environment: The O4 v.t. occurs on predominantly subxeric, Lower Subalpine to Upper Subalpine (1525-2250 m B, 1650-2250 m J), generally steeply sloping sites with southerly aspect. Soils are rapidly to well drained Orthic Eutric Brunisols, Orthic Regosols and Dystric Brunisols on colluvial and morainal landforms.

Vegetation: *Picea engelmannii*, *Abies lasiocarpa*, *Pinus albicaulis*, and *Pinus contorta* are codominant or any one of these species may be dominant in this heterogeneous mixed coniferous v.t. (Plate 38) which has tree cover usually <20% (Table 47). *Pseudotsuga menziesii* occurs in some low elevation stands. The shrub layer has moderate cover (10-45%), the dominants being *Juniperus communis* (3-20%) and *Shepherdia canadensis*

EPIPHYTES										
Lotharia vulpina	--	.5	.5	.5	--	--	.5	--	--	--

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

(<15%). The herb-dwarf shrub layer also has moderate cover (10-30%) and is dominated by *Elymus innovatus* (3-15%), *Arctostaphylos uva-ursi* (3-25%), *Linnaea borealis* (<10%), *Zygadenus elegans* (<3%), and *Fragaria virginiana* (<10%). The bryoid layer has usually low cover (<15%) with few species of high frequency. *Pleurozium schreberi* and *Dicranum* spp. may be locally abundant while *Cladonia* spp., *Peltigera rufescens* and *Peltigera aphthosa* are the predominant lichens.

Successionally, O4 is intermediate to mature often with several age classes represented.

The O4 v.t. is distinguished from other open forest types by the usual codominance or dominance of *Pinus albicaulis*. Stands transitional to C3 at low elevations and to O10 at high elevations occur.

Other Studies: Several of the timberline types described by Baig (1972) for the Alberta Rocky Mountains show strong similarity: *Abies-Pinus albicaulis-Picea/Phyllodoce*, *Pinus albicaulis-Picea-Abies/Juniperus communis*, *Pinus albicaulis-Abies/Salix vestita*, *Picea-Pinus albicaulis/Salix glauca*, and *Abies-Pinus albicaulis*. Hettinger (1975) described a similar type in Jasper (*Picea-Pinus albicaulis/Juniperus communis/Elymus*). In Montana, Pfister et al. (1977) described a *Pinus albicaulis-Abies lasiocarpa* type which is similar to the more mesic Banff-Jasper vegetation while his *Pinus albicaulis* type is similar to more xeric Banff-Jasper *Pinus albicaulis* open forest.

O5: *Pseudotsuga menziesii/Juniperus communis/Arctostaphylos uva-ursi*

(Douglas fir/juniper/bearberry)

Environment: The O5 Douglas fir forest occurs on xeric to subxeric Montane (1320-1520 m), moderate to steeply sloping erosional scarps with southerly aspects; e.g. above the Bow River. Soils are very rapidly to rapidly drained Regosols and Orthic Eutric Brunisols developed on gullied glacial landforms. These sites are among the warmest and driest in the parks.

Vegetation: *Pseudotsuga menziesii* (5-25%) is the dominant tree (Table 48). *Picea glauca* (<5%) is present in one-half the sampled stands. Total tree cover is 5 to 55% (Plate 39). The shrub layer has low to moderate cover (12-55%) and is dominated by *Juniperus communis* (5-15%) and *Pseudotsuga menziesii* regeneration (5-25%) with lesser amounts of *Rosa acicularis* (<2%) and *Spiraea lucida* (≤1%). The herb-dwarf shrub layer has moderate cover (35-60%) with characteristic species being *Arctostaphylos uva-ursi* (5-40%), *Senecio canus* (1-8%), *Agropyron spicatum* (5-20%), *Koeleria cristata* (<6%), and *Galium boreale* (≤2%). Bryophyte and lichen cover is low (<1%) and sporadic, and epiphytes are scarce.

EPIPHYTES						
Letharia spp.	--	--	--	.5	--	--
Parmelia spp.	--	--	--	.5	--	--

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The O5 v.t. is successionally mature with stands 75 to >300 years old.

The O5 v.t. is distinguished from O2 by the absence of *Pinus flexilis* and less frequent occurrence of *Juniperus scopulorum* but occurs in very similar environments. The O5 v.t. is distinguished from C1 by having high *Arctostaphylos uva-ursi* and *Agropyron spicatum* cover and low *Elymus innovatus* cover.

Other Studies: Similar types have been described by Kuchar (1973) in Waterton Lakes National Park (conifer savanna, dominated by *Pseudotsuga menziesii*), Kuchar (1978) in Yoho National Park (Douglas fir/common juniper), and also in southern British Columbia, by Beil (1974, *Pseudotsuga menziesii/Arctostaphylos uva-ursi*).

O6: *Picea engelmannii-Abies lasiocarpa/Salix* spp./*Aulacomnium palustre*

(Engelmann spruce-subalpine fir/willow/ribbed bog moss)

Environment: The O6 v.t. occurs on hygric to hydric, Subalpine (1500-2000 m) gently sloping sites of various aspect. Soils are predominantly poorly and very poorly drained Gleysols and Terric Mesisols developed on fluvial landforms.

Vegetation: *Picea engelmannii* (3-15%) is the dominant tree (Table 49). *Abies lasiocarpa* is occasionally present with cover <5%. Total tree cover is generally <15% (Plate 40). The shrub layer is usually dense (15-80%) and dominated by *Salix glauca* (5-20%) although *S. barrattiana* (10-15%) may be dominant at higher elevations. *Betula glandulosa* (<15%) and *Ledum groenlandicum* (<15%) are usually present. *Potentilla fruticosa* (1-10%) is often present also. The herb-dwarf shrub layer is well developed (30-100%) and is dominated by *Carex* spp. of which *Carex vaginata* (5-30%) and *Carex aquatilis* (10-40%) are usually most abundant. Other common herbs are *Equisetum arvense* (1-15%), *Equisetum variegatum* (<2%), and *Pedicularis bracteosa* (<3%). *Arctostaphylos rubra* (<5%), *Empetrum nigrum* (1-3%), and *Kalmia polifolia* (<5%) often occur on better drained hummocks. The bryoid layer is generally well developed (20-90%) with the dominant species being *Aulacomnium palustre* (10-40%) and *Tomenthypnum nitens* (10-35%). Terrestrial lichens and epiphytes are sparse.

Successionally, O6 is mature with open canopies being maintained by excessive wetness. Stand age may exceed 300 years.

Table 49 Stands representing the Engelmann spruce-subalpine fir / willow / ribbed bog moss (06) v.t.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The O6 v.t. is distinguished from O18 by being much wetter and having more abundant *Carex* spp. Sparsely treed stands may be transitional to S1.

Other Studies: Descriptions of similar types by other authors were not found.

O7: *Picea glauca-Picea mariana/Triglochin maritima-Carex* spp.

(spruce/arrowgrass-sedge)

Environment: The O7 v.t. occurs on hygric to subhydric Montane sites (1000-1200 m) on level to very gentle slopes of various aspect, primarily in the Athabasca valley below Jasper townsite. The soils are poorly drained Gleysols on fluvial landforms. Stands of O7 often have a hummocky microtopography.

Drepanocladus revolvens	-- .5 .5 -- 17
Tomenthypnum nitens	35 .5 .5 .5 03

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The tree layer is open with <15% cover (Table 50). *Picea glauca* and *Picea mariana* are dominant. The shrub layer is moderately dense (15-30%) and is dominated by *Potentilla fruticosa*, *Salix* spp. (especially *Salix myrtillifolia* and *Salix candida*), and *Betula pumila*. Total herb-dwarf shrub layer cover is 30 to 60% with *Triglochin maritima*, *Carex* spp. (especially *Carex aquatilis*, *Carex aurea*, and *Carex capillaris*), *Juncus balticus*, *Tofieldia glutinosa*, and *Equisetum arvense* most important. The bryoid layer usually has a total cover of <35% since there are often patches of marly, bare mineral soil. The most common species are *Tomenthypnum nitens*, *Drepanocladus revolvens*, *Campylium stellatum*, and *Ditrichum flexicaule*.

The O7 v.t. is mature successionally.

The O11 v.t. differs from O7 in occurring at higher altitudes and by having *Ledum groenlandicum* the dominant shrub. Also, O7 generally lacks *Sphagnum* spp. in the bryoid layer.

Other Studies: Jacques and Legge (1974) described a similar type (*Picea/Carex* spp.) from the Kananaskis area.

O9: *Picea engelmannii-Abies lasiocarpa/Valeriana sitchensis-Erigeron peregrinus*

(Engelmann spruce-subalpine fir/valerian-fleabane)

Environment: The O9 v.t. occurs on mesic to subhygric Upper Subalpine sites (2000-2310 m B, 1800-2100 m J) on various slopes and aspects. Soil drainage ranges from well to poorly drained with seepage often present. Seasonality of seepage may account partly for the wider range of drainage classes compared with the moisture regime range (mesic to subhygric). The soils are similarly varied, consisting of Eutric and Dystric Brunisols, Orthic Melanic Brunisols and Gleysols. The landforms are morainal and fluvial.

Vegetation: The tree layer is open with 5 to 20% cover and is dominated by *Picea engelmannii* (5-20%) and *Abies lasiocarpa* (5-10%) (Table 51). The shrub layer is generally sparse (<15%) with *Abies lasiocarpa* (5-10%) and *Picea engelmannii* (1-5%) most common. The herb-dwarf shrub layer is species-rich and has a total cover of 60 to 90% (Plate 41). Dominant species are *Valeriana sitchensis* (5-15%), *Erigeron peregrinus* (5-10%), *Trollius albiflorus* (5-10%), *Vaccinium scoparium* (5-15%), and *Cassiope mertensiana* (5-10%). *Artemisia norvegica* (5-10%) is characteristic of Jasper stands, although *Artemisia norvegica* also occurs in Banff north of the North Saskatchewan River. *Erythronium grandiflorum* (5-10%) is likewise characteristic of Banff stands, but it also extends to northern Jasper. Other important species are *Pedicularis bracteosa* (1-3%), *Senecio triangularis* (1-20%), *Anemone occidentalis* (2-5%), and *Phyllodoce empetriformis* (1-5%). Common species with low cover include *Antennaria lanata*, *Arnica cordifolia*, *Fragaria virginiana*, *Sibbaldia procumbens*, *Veratrum eschscholtzii*, and, in northern Jasper, *Lupinus nootkatensis*. Bryoid cover is variable (1-80%) with *Dicranum scoparium*, *Drepanocladus uncinatus*, *Aulacomnium palustre*, *Barbilophozia lycopodioides*, *Cladonia* spp., and *Peltigera aphthosa* most common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Stands of O9 are generally 100 to 300 years old and are mature successionally.

The O9 v.t. is differentiated from O10 by being moister and dominated by herbs rather than dwarf shrubs. The H16 v.t. has many species in common with O9, but lacks tree cover. Stands which intergrade with O10 or H16 occur.

Other Studies: Similar types have been described by Baig (1972) for the Alberta Rockies (*Pinus albicaulis-Abies-Picea/Valeriana sitchensis*), Trottier and Scotter (1973) for Banff (*Picea-Abies/Trollius albiflorus/Carex* spp.), and Habeck (1969) described a similar type for Logan Pass, Glacier National Park, Montana.

O10: ***Picea engelmannii-Abies lasiocarpa/Phyllodoce glanduliflora-Cassiope mertensiana***

(Engelmann spruce-subalpine fir/heather)

Environment: The O10 v.t. open forests occur on mesic Upper Subalpine (1830-2150 m J; 1920-2400 m B), level to steeply sloping sites of predominantly northerly aspect. Soils are well drained Dystric and Eutric Brunisols, and Orthic Humo-Ferric Podzols developed primarily on morainal and colluvial landforms and to a lesser extent on fluvial, glaciofluvial, and residual landforms.

Parmeliopsis ambigua	--	--	--	--	.5	.5	--	--	--	.5
Alectoria spp.	.5	--	.5	--	.5	--	--	--	--	--

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: *Picea engelmannii* (<20%) is the dominant tree and *Abies lasiocarpa* (<20%) is often codominant (Table 52). Total tree cover is generally <20% (Plate 42). The shrub layer has low to high cover (10-55%) and is dominated by *Abies lasiocarpa* (10-50%) and *Picea engelmannii* (5-10%) regeneration. The herb-dwarf shrub layer has moderate to high cover (30-85%) due mainly to the high cover of the heaths, *Phyllodoce glanduliflora* and *Phyllodoce empetriformis* (5-50%), *Cassiope mertensiana* (10-50%), and *Vaccinium scoparium* (5-25%). Also characteristic are *Antennaria lanata* (<10%) and *Pedicularis bracteosa* (<5%). The bryoid layer has low to high cover (5-75%) and is dominated by *Barbilophozia lycopodioides* (5-50%) and *Dicranum scoparium* (5-25%). *Hylocomium splendens* and *Pleurozium schreberi* are locally abundant. Common lichens are *Peltigera aphthosa* (<5%), *Cladonia ecmocyna* (<5%), and *Cetraria islandica* (<5%) with total lichen cover 5 to 15%.

The O10 v.t. is successionally mature with most stands 200 to 400 years old.

The O10 v.t. is distinguished from C34 by having a more open physiognomy, less abundant *Hylocomium splendens* and *Pleurozium schreberi*, and by generally higher elevations. The O10 v.t. is distinguished from O9 by being drier and having much lower cover of *Valeriana sitchensis* and *Erigeron peregrinus*. Stands with abundant *Larix lyallii* may be transitional to C23 at the upper elevational limit of O10. At high elevations where 50% or more of an Ecosite is without trees and vegetation is heath dominated, these sites have been described as L5 > O10 such as on the Egypt 4, Larch Valley 2, and Peyto Lake 4 Ecosites.

Other Studies: In Jasper, La Roi (1975, *Picea engelmannii/Phyllodoce* types) and Eeil (1966) have described similar types. In other parts of Alberta, similar types have been described by Bai; (1972, *Abies-Picea/Phyllodoce*), Kirby and Ogilvie (1969, Krummholz/*Vaccinium scoparium*), Ogilvie (1976, *Phyllodoce-Vaccinium scoparium*), and Johnson (1975, *Picea engelmannii-Phyllodoce glanduliflora*). In British Columbia, McLean (1970, *Abies lasiocarpa-Vaccinium scoparium*) and Kuchar (1978, alpine fir forest in part) have described similar types.

O11: *Picea* spp./*Ledum groenlandicum/Tomenthypnum nitens*

(spruce/Labrador tea/brown moss)

Environment: The O11 v.t. occurs on hygric to subhydric, Montane to Lower Subalpine sites (1330-1770 m) on nearly level to very gentle slopes of various aspect in Banff and Jasper. The soils are poorly to very poorly drained Rego Gleysols and Terric Mesisols on glacial and glaciolacustrine landforms. Fluvial and organic veneers are common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The tree layer is open with a total cover of 5 to 20% (Table 53, Plate 43). The dominant tree in Jasper and northern Banff is *Picea mariana* (5-15%). *Picea mariana* does not occur south of Bow Pass in Banff, thus in southern Banff the dominant is *Picea glauca* or a *Picea glauca* x *Picea engelmannii* hybrid. The shrub layer is moderately dense (20-50%) and is dominated by *Ledum groenlandicum* (10-15%) and *Betula glandulosa* (5-15%), with lesser amounts of *Potentilla fruticosa* (3%) and *Salix glauca* (3%). *Salix myrtillifolia* (5%) is a common component in Jasper. The herb-dwarf shrub layer is dense (40-80%) and species-rich. Common species are *Carex aquatilis*

(10-20%), *Carex vaginata* (1-3%), *Equisetum arvense* (5-10%), and *Vaccinium vitis-idaea* (1-2%). Species with low cover but high frequency include *Carex capillaris*, *Equisetum scirpoides*, and *Oxycoccus microcarpus*. *Arctostaphylos rubra* (1-3%) occurs in many Jasper stands and *Empetrum nigrum* (2-5%) occurs in many Banff stands. The hummocky ground surface has a nearly complete cover of mosses. Hollows and the lower portions of hummocks are occupied by *Tomenthypnum nitens* (20-25%), *Aulacomnium palustre* (5-10%), and *Sphagnum warnstorfii* (3-5%). Hummock tops and other drier sites contain *Sphagnum fuscum* (5-15%), *Hylocomium splendens* (5-20%), *Cladonia mitis* (1-3%), and *Peltigero aphthosa* (<1%) .

Stands of the O11 v.t. are 100 to 250 years old and are mature successionally. *Picea* spp. regeneration is present in nearly all stands.

The O11 v.t. is distinguished from O6 by having *Ledum groenlandicum* the dominant shrub rather than *Salix* spp.. The O11 v.t. also occurs in both Montane and Lower Subalpine, while O6 occurs only in Lower Subalpine.

Other Studies: Similar types have been described by Raup (1947) for the southwestern Northwest Territories (muskeg forest), Kirby and Ogilvie (1969, Ogilvie 1963, *Picea/Sphagnum-Ledum*), and Jacques and Legge (1974, *Picea/Sphagnum-Ledum*) for the Kananaskis area of Alberta. In Jasper, Laidlaw (1971) described a similar type *(Picea mariana/Tomenthypnum*) as did La Roi (1975, *Picea mariana/Ledum groenlandicum/Equisetum arvense-Carex* spp.)

O12: *Picea engelmannii-Abies lasiocarpa/Salix vestita/Arctostaphylos rubra*

(Engelmann spruce-subalpine fir/rock willow/ alpine bearberry)

Environment: The O12 v.t. occurs on mesic to subhygric, usually Upper Subalpine (1500-2100 m), moderate to steep, north facing slopes primarily in Jasper. The soils are generally well to moderately well drained Eutric Brunisols and Regosols developed on colluvial, fluvial and morainal landforms.

Vegetation: *Picea engelmannii* is the predominant canopy tree (Plate 44) with 2 to 30% cover, but generally <15% (Table). *Abies lasiocarpa* is present in about 50% of the stands sampled with cover <10%. *Pinus contorta* and *Pinus albicaulis* occur occasionally. The shrub layer is usually dense (30-70%) and is dominated by *Salix vestita* (10-35%) and *Abies lasiocarpa* (3-15%). The herb-dwarf shrub layer is moderately well developed (20-50%) and is dominated by *Arctostaphylos rubra* (3-15%) and *Dryas octopetala* (3-10%). *Cassiope tetragona* and *Linnaea borealis* may attain cover of 40% and 30% respectively but may be absent. The bryoid layer is generally moderately well developed (15-45%) though few species are abundant in a large proportion of O12 stands. The pre-

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

dominant mosses are *Hylocomium splendens* and *Dicranum scoparium*. Epiphytes are generally sparse.

Successionally O12 is mature, its open physiognomy being maintained by sporadic colluviation.

The O12 v.t. is distinguished from O14 by being drier and less herb-rich and by the presence of *Dryas octopetala* in O12. Sparsely treed stands may be transitional to S2.

Other Studies: No similar type has been described.

O14: *Picea engelmannii-Abies lasiocarpa/Salix vestita/Pedicularis bracteosa*

(Engelmann spruce-subalpine fir/rock willow/bracted lousewort)

Environment: The O14 v.t. occurs on subhygric to hygric, usually Upper Subalpine (1500-2140 m), moderate to steep, north facing slopes, primarily in Banff. The soils are imperfectly to poorly drained Gleysols developed on morainal and to a lesser extent on fluvial landforms.

Vegetation: *Picea engelmannii* is the dominant tree with 5 to 75% cover but generally <20% (Plate 45), though closed forests occur in nearly one-half of the stands sampled (Table 55). *Abies lasiocarpa* is usually present with cover <10%. *Pinus contorta* occurs sporadically with cover <10%. The shrub layer is usually dense (15-95%) and is dominated by *Salix vestita* (5-50%) and *Abies lasiocarpa* (10-20%). The herb-dwarf shrub layer is lush with a cover of 40 to 70% and is dominated by *Pedicularis bracteosa* (1-5%), *Polygonum viviparum* (<3%), *Erigeron peregrinus* (1-3%), *Vaccinium scoparium* (2-15%), and *Anemone parviflora* (<3%). *Potentilla fruticosa* (3-8%), *Empetrum nigrum* (2-8%), and *Stenanthium occidentale* (1-5%) occur in over one-half of the sampled stands. The bryoid layer is moderately well developed (40-70%) and is dominated by *Pleurozium schreberi* (5-15%), *Barbilophozia* spp. (3-10%), and *Aulacomnium palustre* (10%). *Peltigera aphthosa* is the most abundant lichen (<5%).

The O14 v.t. is mature successionally.

The O14 v.t. is distinguished from O12 by being wetter and having greater cover of trees, herbs, dwarf shrubs, and mosses. Species richness is greater in O14.

Other Studies: Similar types were described by Baig (1972) for the Alberta Rocky Mountains *(Abies-Picea/Salix vestita)* and by Kondla (1978) for the Kananaskis area of Alberta (spruce/willow).

O16: ***Betula papyrifera/Betula occidentalis/ Arctostaphylos uva-ursi***

(paper birch/bearberry)

Environment: Open birch forests of the O16 v.t. occur on subxeric, Montane (1250 m) moderately steep, southerly aspects in the east gate area of Jasper. Soils are predominantly rapidly drained Cumulic Regosols on eolian landforms. Loess [illegible]ill being deposited on these sites.

Vegetation: Although tree cover is sparse (<10%) (Table 56), individual *Betula papyrifera* trees may attain heights of 17 m and dbh's of 20 cm (Plate 46). The shrub stratum which has moderate cover (20%) is dominated by *Betula occidentalis* (10%) with lesser amounts of *Juniperus communis* (3%) and *Potentilla fruticosa* (2%). The herb-dwarf shrub layer has cover of 45%, dominated by *Arctostaphylos uva-ursi* (40%) with lesser cover of *Elymus innovatus* (3%), *Aster conspicuus* (2%), *Carex concinna* (2%), *Zygadenus elegans* (1%), *Anemone multifida* (1%), and *Carex scirpoidea* (1%). The bryoid layer has 1% cover.

Taraxacum officinale	.5
Zygadenus elegans	01

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally O16 is intermediate to mature with the possibility that *Picea glauca* cover may increase since sporadic *Picea glauca* regeneration occurs.

The O16 v.t. is a minor associate in Talbot 3 (TA3), its occurrence being greater than the one sampled stand indicates. This v.t. is unique in being the only one that has *Betula papyrifera* and *Betula occidentalis* as dominants, these species being absent or very uncommon in most of the Banff - Jasper area. Stands with less *Betula* spp. and more *Picea glauca* are transitional to O17.

Other Studies: No similar type has been described by other workers.

O17: ***Picea glauca/Juniperus communis/Arctostaphylos uva-ursi***

(white spruce/juniper/bearberry)

Environment: The O17 v.t. occurs predominantly on subxeric to mesic, Lower Subalpine sites (1550-2030 m) on various slopes of southerly and westerly aspect. The soils are rapidly to well drained Orthic Eutric Brunisols and Orthic Regosols on colluvial, fluvial, and morainal landforms, and to a lesser extent on eolian landforms.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: *Picea glauca* (10-20%) dominates the open tree layer (Table 57, Plate 47). The *Picea* ranges from *Picea glauca* at lower altitudes, through *Picea glauca* X *Picea engelmannii* hybrids at intermediate altitudes, to *Picea engelmannii* at higher altitudes. The shrub layer has moderate cover (15-35%) and is dominated by *Juniperus communis* (5-20%), *Shepherdia canadensis* (3-15%), and *Rosa acicularis* (1-5%). The herb-dwarf shrub layer has a total cover of 20 to 50%. *Arctostaphylos uva-ursi* (10-25%), *Elymus innovatus* (5-15%) and *Linnaea borealis* (3-5%) are dominant. Other characteristic species with low cover are: *Juniperus horizontalis*, *Zygadenus elegans*, *Fragaria virginiana*, *Hedysarum sulphurescens* (Banff), and *Hedysarum alpinum* (Jasper). The bryoid layer (5-10%) is sparse. Common species include *Thuidium abietinum*, *Ditrichum flexicaule*, *Tortula ruralis*, *Peltigera rufescens*, and *Peltigera canina*. Epiphytes are scarce with *Letharia vulpina*, *Parmeliopsis ambigua*, and *Cetraria pinastri* usual.

Successionally, O17 is intermediate to mature with stands 60 to 300 years old.

The O17 v.t. is closely related to O3 and intermediate stands occur. The O17 v.t. is differentiated from O3 by the absence or low cover (<1%) of *Potentilla fruticosa*, an altitude generally >1500 m (Lower Subalpine), a landform usually colluvial or morainal, and a Brunisolic soil or, if the landform is colluvial, the soil may be Regosolic. If the landform is fluvial, the soil is usually Brunisolic rather than Regosolic as in O3. In contrast, O3 generally has *Potentilla fruticosa* with >1% cover, the altitude is <1500 m (Montane), the landform is fluvial, and the soil is Regosolic.

Other Studies: Similar types have been described from as far north as southern Yukon (Douglas 1974, *Picea glauca-Shepherdia canadensis*) and southwestern Northwest Territories (Raup 1947, *Picea glauca/Juniperus communis/Arctostaphylos uva-ursi*). In Alberta, similar types have been described from the Kananaskis area (Kirby and Ogilvie 1969, *Picea/Arctostaphylos*; Jacques and Legge 1974, *Picea/Shepherdia canadensis-Arctostaphylos uva-ursi*; and Kondla 1978, spruce/juniper-lichen and spruce/buffaloberry-lichen). Ogilvie (1963) described a similar type in the Alberta Rockies (*Picea/Arctostaphylos*). In British Columbia, Kuchar (1978) described a similar type (spruce/juniper-bearberry) in Yoho National Park.

O18: ***Picea engelmannii-Abies lasiocarpa/Salix glauca/Elymus innovatus***

(Engelmann spruce-subalpine fir/willow/hairy wild rye)

Environment: The O18 v.t. occurs on mesic Lower to Upper Subalpine sites (1710-2250 m) on moderate to steep slopes of mostly southerly or westerly aspect in eastern Banff and Jasper. The soils are well drained Orthic Eutric Brunisols and Regosols predominantly on fluvial and colluvial landforms, and to a lesser extent on morainal landforms.

Vegetation: The O18 v.t. is an open forest (Plate 48) with a total tree cover of 10 to 20% (Table 58). *Picea engelmannii* (5-20%) is dominant. *Abies lasiocarpa* (≤5%) is often present. Total shrub cover is 10 to 40% with *Salix glauca* (5-30%) dominant. *Shepherdia canadensis* (≤2%) is usually present. The herb-dwarf shrub layer is well developed with 20 to 80% cover. *Elymus innovatus* (10-55%) is dominant and *Arctostaphylos uva-ursi* (2-15%) is usually present. In Banff, *Hedysarum sulphurescens* (5-25%) is frequently present and in Jasper *Hedysarum alpinum* (2-10%) is usual. Other species with high frequency but low cover are *Achillea millefolium*, *Epilobium angustifolium*, *Senecio lugens* (Banff), and *Fragaria virginiana*. Bryoid cover is variable but usually sparse. *Drepanocladus uncinatus*, *Peltigera aphthosa* and *Cladonia pyxidata* are often present with <1% cover. Epiphytes are scarce.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Ages of O18 stands range from 60 to >300 years. *Picea engelmannii* regeneration of all age classes is common in many stands. Even though some of the 60 to 80 year old stands might be considered intermediate, they are indistinguishable in composition and structure from the older stands. Thus, O18 is considered to be mature successionally. O18 appears to develop, following fire, by *Picea engelmannii* invasion of a shrub type like S12, which is often adjacent to O18 stands.

The O18 v.t. is distinguished from C33 by having an open forest structure and well-developed shrub layer in which *Salix glauca* is dominant.

Other Studies: No similar type has been described by other workers.

O19: *Picea engelmannii-Abies lasiocarpa/Dryas octopetala*

(Engelmann spruce-subalpine fir/mountain avens)

Environment: The O19 v.t. occurs on mesic Upper Subalpine sites (2030-2350 m) primarily in eastern Banff and northern Jasper mostly on steep slopes of various aspects. The soils are well drained Orthic Eutric and Melanic Brunisols on colluvial and morainal landforms. Solifluction is common.

Tortella fragilis	--	--	.5	.5	--	--	--	--	--	--
Tortula ruralis	--	--	02	.5	--	01	--	--	10	05

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The open tree layer has 10 to 20% cover and is often stunted (≤5 m), (Table 59). *Picea engelmannii* (5-20%) and *Abies lasiocarpa* (5-15%) are dominant (Plate 49). The shrub layer is sparse to absent with *Picea engelmannii* and *Abies lasiocarpa* most common. Total herb-dwarf shrub cover is 30 to 80% with *Dryas octopetala* (15-45%) dominant. Other important species are *Salix arctica* (1-5%), *Carex* spp. (1-5%), *Arctostaphylos rubra* (1-3%), *Arctostaphylos uva-ursi* (<5%), *Artemisia norvegica* (Jasper) (1-2%), and *Zygadenus elegans* (1-2%). *Polygonum viviparum*, *Poa alpina*, *Sedum stenopetalum*, and *Potentilla diversifolia* occur frequently but with low cover. Bryoid cover is variable (5-45%). Common species include *Tortula ruralis*, *Tortula norvegica*, *Thuidium abietinum*, *Cetraria ericetorum*, *Cetraria islandica*, *Cetraria nivalis*, and *Cetraria cucullata*. Bare soil often covers 15 to 25% of the site.

The O19 v.t. is mature successionally and usually occurs near the upper elevational boundary of the Upper Subalpine in sites similar to those of O10 but more exposed and with less stable soils. The O19 v.t. differs from O10 in having *Dryas octopetala* dominant rather than *Phyllodoce glanduliflora* or *Cassiope mertensiana* in the herb-dwarf shrub layer.

Other Studies: Baig (1972) described a similar timberline type from the Alberta Rocky Mountains (*Abies-Picea/Dryas octopetala*).

S1: *Betula* spp.-*Potentilla fruticosa-Salix glauca/Tomenthypnum nitens*

(dwarf birch-shrubby cinquefoil-willow/brown moss)

Environment: The S1 v.t. occurs on subhygric to hydric Montane to Upper Subalpine (1350-2230 m B; 1360-2030 m J), level to gently sloping sites of various aspects. Soils are poorly to very poorly drained Gleysols and Terric Mesisols developed on fluvial and morainal landforms.

Vegetation: Tree cover is absent or sporadic (Plate 50) and this v.t. is dominated by shrubs (35-70%) (Table 60). *Betula glandulosa* or *Betula pumila* (5-20%) dominate with codominant *Potentilla fruticosa* (5-25%) and *Salix glauca* (10-40%). The herb-dwarf shrub layer has high cover (60-80%) but composition is variable with the dominant species being *Carex aquatilis* (10-40%), *Deschampsia caespitosa* (10-25%), *Rubus acaulis* (<5%), and *Pedicularis groenlandica* (<3%). The bryoid layer also has high cover (40-90%), the dominants being *Tomenthypnum nitens* (15-60%), *Aulacomnium palustre* (<20%), *Drepanocladus revolvens* (10-40%), and *Campylium stellatum* (<20%). Lichens are generally absent.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally S1 is mature.

The S1 v.t. is distinguished from S3 by the absence or very low abundance of *Scirpus caespitosus* which is the dominant herb in S3. The S1 has a generally wetter environment, lower elevation and low *Salix barrattiana* and *Erigeron peregrinus* cover compared with S4. The S1 v.t. differs from S9 and S10 by being much wetter, having much less *Kobresia myosuroides* than S9 and much more gentle slopes than S10.

Other Studies: In Alberta, similar types have been described by Jeffrey et al. (1968, *Salix-Potentilla-Betula*) and by Kondla (1978) in Kananaskis Provincial Park (birch-willow wetland). In British Columbia, Kuchar (1978) described a dwarf birch shrub meadow in Yoho National Park.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

S2: *Abies lasiocarpa-Salix* spp./*Valeriana sitchensis*

(subalpine fir-willow)

Environment: The S2 v.t. occurs on mesic to subhygric, Lower to Upper Subalpine (1600 - 2100 m J, - 2240 m B) steeply sloping snow avalanche paths on various aspects. Soils are predominantly Regosols and Eutric and Dystric Brunisols developed on colluvial landforms.

Vegetation: Dwarfed *Abies lasiocarpa* (10-70%) is the dominant shrub (Table 61). *Salix vestita* (10-20%) and *Salix glauca* (5-30%) occur in most plots but with generally lower cover than *Abies*, with combined *Salix* spp. cover 20 to 60% (Plate 51). *Rhododendron albiflorum* and *Menziesia glabella* may be abundant in some stands, particularly in western portions of Banff and Jasper. The herb-dwarf shrub layer is usually well developed (20-70%) and is dominated by *Valeriana sitchensis* (<15%), *Epilobium angustifolium* (<10%), *Artemisia norvegica*, (Jasper, <20%), *Thalictrum occidentale* (<15%), and *Pedicularis bracteosa* (<12%). The bryoid layer is generally poorly developed although *Pleurozium schreberi*, *Barbilophozia* spp., or *Brachythecium* spp. may locally account for >30% cover. Epiphytic lichens are sparse.

The moist conditions of S2 separate it from the generally dry S10, also strongly influenced by avalanching. Some stands are transitional to H5 on sites with low shrub cover.

The varying avalanche frequency in conjunction with other environmental factors results in variable though more or less stable vegetation of stunted physiognomy. Thus, S2 is best considered mature successionally, although it has characteristics of earlier successional stages.

Other Studies: Similar vegetation was described by Butler (1979) in Glacier National Park, Montana, by Trottier and Scotter (1973) on avalanche paths in Banff (*Picea-Abies/Alnus crispa-Vaccinium scoparium/Heracleum lanatum*), and by Kuchar (1978) in Yoho National Park (deciduous avalanche scrub).

S3: *Betula glandulosa-Potentilla fruticosa/Scirpus caespitosus/Drepanocladus revolvens* (dwarf birch-shrubby cinquefoil/needlerush)

Environment: The S3 v.t. occurs on subhydric to hydric, Lower Subalpine sites (1450-1900 m) on nearly level slopes of various aspects. The soils are poorly to very poorly drained Terric Mesisols and Orthic Gleysols on glacial, glaciolacustrine, and fluvial landforms.

Vegetation: The shrub layer (Plate 52) has a total cover of 5 to 25% with *Betula glandulosa* (2-15%) and *Potentilla fruticosa* (<1-15%) dominant (Table 62). *Salix barrattiana* and *Ledum groenlandicum* often occur with low cover. The herb-dwarf shrub layer is dominated by herbs and has a total cover of 60 to 95%. *Scirpus caespitosus* (20-80%) is dominant with *Carex aquatilis* (5-15%) and *Pedicularis groenlandica* (1-5%) being the other main species. Common species with low cover values include *Anemone parviflora*, *Eriophorum angustifolium*, *Antennaria lanata*, *Carex capillaris*, *Deschampsia caespitosa*, *Polygonum viviparum*, *Equisetum arvense*, and *Equisetum variegatum*. Total bryoid layer cover is 60 to 90% with mosses predominant. Important species are *Drepanocladus revolvens* (20-80%), *Tomenthypnum nitens* (5-40%), and *Campylium stellatum* (1-30%). *Aulacomnium palustre* and *Sphagnum warnstorfii* occur frequently but usually with low cover.

S3 is mature successionally, and is distinguished from other wet shrub v.t.s, including S1, by the dominance of *Scirpus caespitosus* in the herb-dwarf shrub layer.

Other Studies: Kuchar (1978) described a deer hair bulrush meadow in Yoho National Park, British Columbia.

S4: *Salix* spp.-*Betula glandulosa/Erigeron peregrinus*

(willow-dwarf birch/fleabane)

Environment: The S4 v.t. occurs on hygric to mesic, predominantly Upper Subalpine sites (1850-2300 m) on nearly level to moderate slopes on all aspects. The soils are Gleysols,

Regosols, and Eutric Brunisols. Drainage is mostly moderately well to poor, although both well and very poorly drained sites also occur. The wide range of moisture regime and drainage class suggests a fluctuating water table in these sites. The landforms are fluvial and morainal.

Vegetation: *Salix glauca* (10-45%) is typically the dominant shrub (Table 63). *Betula glandulosa* (10-50%) is often dominant to codominant with *Salix glauca*, but may be absent. *Salix barrattiana* (5-20%) is often present but never dominant. Total shrub cover is 45 to 85% (Plate 53). Total herb-dwarf shrub layer cover is 35 to 70% with herbs much more important than dwarf shrubs. Common dominants include *Erigeron peregrinus* (3-10%), *Fragaria virginiana* (1-10%), *Potentilla diversifolia* (1-3%), and *Artemisia norvegica* (Jasper), (1-5%). Other common species with low cover are *Achillea millefolium*, *Phleum alpinum*, *Trollius albiflorus*, and *Valeriana sitchensis*. Bryoid layer cover is generally 15 to 35% with *Aulacomnium palustre*, *Drepanocladus uncinatus*, *Tomenthypnum nitens*, *Dicranum scoparium*, and *Peltigera rufescens* most common.

The S4 v.t. is mature successionally.

The S4 v.t. is differentiated from the very similar S12 by having <10% cover of *Elymus innovatus* and greater cover of *Betula glandulosa* and *Salix barrattiana*. The S10 v.t. is drier than S4, being typically mesic to subxeric, well to rapidly drained, without gleyed soils or *Salix barrattiana* but often with *Arctostaphylos uva-ursi*. *Betula glandulosa* may be dominant to codominant in S10. The S8 v.t. is differentiated by *Salix barrattiana* being dominant. Intergrades between S4 and S8, S10 or S12 occur.

Other Studies: Similar vegetation has been described in the Kananaskis area of Alberta by Kirby and Ogilvie (1969) and by Kondla (1978, birch wetland).

S6: *Salix scouleriana-Alnus crispa/Mertensia paniculata*

(willow-green alder/bluebell)

Environment: The S6 v.t. occurs on subhygric to hygric, Lower Subalpine sites (1300-1600 m) on moderate slopes of northerly aspect in Jasper. The soils are moderately well drained Orthic Eutric Brunisols with seepage, on morainal landforms.

Vegetation: The S6 v.t. is dominated by tall shrubs (Plate 54) usually 3 to 10 m high (Table 64). This upper shrub layer is dense (35-90%) and dominated by *Salix scouleriana* (10-60%) and *Alnus crispa* (10-80%). Some stands have *Alnus tenuifolia* (10-30%). The lower shrub layer (0.5-2 m high) has a total cover of 20 to 25% and is dominated by *Rosa acicularis* (5-15%) with lesser amounts of *Rubus strigosus* (7%), *Viburnum edule* (3%), and *Lonicera involucrata* (1%). Herb-dwarf shrub cover is 25 to 50% commonly with *Mertensia paniculata* (2%), *Cornus canadensis* (5%), *Rubus pubescens* (4%), and *Calamagrostis canadensis* (3%). Other species with high frequency but low cover include *Epilobium angustifolium, Galium triflorum, Viola renifolia,* and *Moneses uniflora.* Bryophytes and lichens, both terrestrial and epiphytic, are scarce.

Stands of the S6 v.t. often contain a few *Pinus contorta* trees but succession to a forest like C10 does not appear likely. Thus, S6 is regarded as a mature successional stage.

The S6 v.t., dominated by tall willow and alder, is quite distinct from other v.t.s.

Other Studies: No similar type has been described by other workers.

S7: *Salix* spp./*Equisetum arvense*

(willow/horsetail)

Environment: The S7 shrub thickets occur on hygric, Montane to Lower Subalpine (1000-1880 m), level to gently sloping fluvial landforms of various aspects. Soils are imperfectly to poorly drained Rego Gleysols and Regosols that are subject to periodic flooding and sediment deposition.

Vegetation: Tree cover is absent or limited to scattered individuals, particularly on nearly stable floodplains and fans. Shrub cover is high (25-80%, Plate 55) and is comprised largely of one or more of the following *Salix* spp. (Table 65) which may have widely ranging cover values: *Salix glauca, Salix bebbiana, Salix planifolia, Salix myrtillifolia,* and *Salix farrae. Potentilla fruticosa* (<1%) is often present. The herb-dwarf shrub layer is also dense (25-75%) and is as heterogeneous as the shrub layer, a reflection of the early successional stage and consequent random establishment of a wide variety of species, giving this v.t. a weedy appearance. The dominant herb is *Equisetum arvense* (1-25%). Some other more frequently occurring species include *Fragaria virginiana* (<6%), *Achillea millefolium* (<2%), *Vicia americana* (<6%), and *Taraxacum officinale* (<1%) , but many other species may be locally abundant, especially *Carex* spp.. The bryoid layer has generally low cover (<20%) attributable to *Drepanocladus* spp. and several other hydrophytic species.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, S7 is early to intermediate, following H3 and preceding O3 on stable sites.

The S7 v.t. is distinguished from the other shrub v.t.s by its Montane to Lower Subalpine location, abundance of *Equisetum arvense* and its occurrence on recent alluvial locations. Stands transitional to S11 occur at higher elevations.

Other Studies: Descriptions of similar types by other authors were not found.

S8: *Salix barrattiana/Potentilla diversifolia*

(willow/cinquefoil)

Environment: The S8 v.t. occurs on subhygric to hygric Upper Subalpine sites (2000-2380 m B; 1900-2250 m J) on gentle to moderate slopes on mostly northerly and easterly aspects. The soils are moderately well to poorly drained Gleysols and Regosols. Seepage is common through much of the growing season. The landforms are primarily fluvial and to a lesser extent morainal.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The shrub layer (Plate 56) has a total cover of 40 to 75% with *Salix barrattiana* (20-60%) dominant (Table 66). *Salix glauca* (5-20%) is often present also. Total herb-dwarf shrub layer cover is 30 to 70% with herbs much more important than dwarf shrubs. This layer is species-rich with many species having low cover. Common dominants include *Potentilla diversifolia* (1-5%), *Trollius albiflorus* (3-15%), *Erigeron peregrinus* (3-10%), and *Artemisia norvegica*, Jasper (1-10%). Other common species with low cover are *Polygonum viviparum*, *Valeriana sitchensis*, *Pedicularis bracteosa*, *Senecio triangularis*, *Fragaria virginiana*, *Achillea millefolium*, *Castilleja occidentalis*, and *Sibbaldia procumbens*. Bryoid cover is quite variable but usually <30%. Common species include *Aulacomnium palustre*, *Tortula norvegica*, *Bryum pseudotriquetrum*, and *Brachythecium* spp.

The S8 v.t. is mature successionally.

The S8 v.t. is differentiated from other similar shrub v.t.s by *Salix barrattiana* dominance. Intergrades to S4 and S12 occur.

Other Studies: In Banff, similar types have been described by Trottier and Scotter (1973, *Salix barrattiana-Betula glandulosa/Carex* spp., *Salix barrattiana/Carex nigricans*), Beder (1967), Broad (1973), and Knapik et al. (1973). In Jasper, similar types have been described by Crack (1977) and Kuchar (1975). Elsewhere in Alberta, Ogilvie (1976), Mortimer (1978, *Salix barrattiana-Trollius albiflorus*), Jacques and Legge (1974, tall willow), and Trottier (1972) have described similar types.

S9: *Betula glandulosa-Salix glauca/Kobresia myosuroides*

(dwarf birch-willow/kobresia)

Environment: The S9 v.t. occurs on predominantly mesic Lower to Upper Subalpine (1740-2210 m B, 1380-2060 m J), level to gently sloping sites of various aspects in eastern Banff and Jasper. Soils are well to imperfectly drained Regosols, Brunisols, and Rego Gleysols developed on fluvial landforms. The generally coarse soil textures and consequent rapid surface drainage often result in mesic vegetation even though the water table may be at <1m.

Vegetation: *Betula glandulosa* (15-50%) is the dominant shrub (Table 67). Also important are *Salix glauca* (10-30%) and *Potentilla fruticosa* (5-20%), contributing to total shrub cover of 20 to 85% (Plate 57). Herb-dwarf shrub layer cover is generally high (55-90%) dominated by *Kobresia myosuroides* (15-50%). Other characteristic herbs are *Achillea millefolium* (<2%), *Elymus innovatus* (2-15%) and *Fragaria virginiana* (2-8%). The cover of the bryoid layer is generally low (3-15%), the most common species being *Tortula ruralis* (≤5%). *Thuidium abietinum*, *Cetraria ericetorum*, *Cladonia pyxidata*, and *Peltigera rufescens* are other frequently occurring species which usually have ≤1% cover.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The S9 v.t. is successionally mature.

The S9 v.t. is distinguished from other v.t.s with the same shrub dominants (S1, S4, S10, S11) by the dominance of *Kobresia myosuroides* in the herb layer and by the coarser soil textures.

Other Studies: Descriptions of similar types by other authors were not found.

S10: ***Salix glauca-Betula glandulosa-Potentilla fruticosa***

(willow-dwarf birch-shrubby cinquefoil)

Environment: The S10 v.t. occurs on mesic to subxeric, Lower to Upper Subalpine sites (1900-2350 m: B; 1750-2200 m J) on moderate to steep slopes of southerly and westerly aspect, primarily in eastern Banff and eastern and northern Jasper. The soils are well to rapidly drained Brunisols and Regosols. The landforms are mostly colluvial with some fluvial and morainal landforms. The sites are commonly snow avalanched.

Vegetation: Total shrub cover (Plate 58) is typically 30 to 70% with *Salix glauca* (15-40%) dominant (Table 68). *Betula glandulosa* (10-35%) is codominant to dominant, or sometimes absent. *Potentilla fruticosa* (1-3%) and *Juniperus communis* (1-10%) are often present. Scattered *Picea engelmannii* and *Abies lasiocarpa* trees are sometimes present but usually with <5% cover. Total herb-dwarf shrub cover is 40 to 60% with *Arctostaphylos uva-ursi* (10-20%) and *Elymus innovatus* (10-20%) often dominant. Other important species are *Epilobium angustifolium* (1-5%), *Fragaria virginiana* (2-5%), and, in Banff, *Hedysarum sulphurescens* (1-5%). Common species with low cover include *Achillea millefolium, Agoseris glauca* (Banff), *Delphinium glaucum, Potentilla diversifolia, Solidago multiradiata, Poa* spp., and *Zygadenus elegans.* Bryoid cover is low (<10%) with *Tortula ruralis* and *Peltigera* spp. most common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The S10 v.t. is mature successionally.

The S10 v.t. differs from S4, S8 and S12 in being drier as indicated by the absence of gleyed soils, the absence or very low cover of *Salix barrattiana, Trollius albiflorus,* and *Erigeron peregrinus,* and the presence of

Arctostaphylos uva-ursi in most S10 stands. Intergrades between S10 and S4 or S12 occur.

Other Studies: Descriptions of similar types by other authors were not found.

S11: *Salix glauca/Danthonia intermedia*

(willow/timber oatgrass)

Environment: The S11 v.t. occurs on hygric to mesic sites on nearly level to gentle slopes of various aspects. In Banff, S11 occurs in the Upper Subalpine (1850-2200 m) throughout the park, while in Jasper it occurs in the Lower Subalpine (1400-1750 m) with nearly all stands north of Highway 16. The soils include Gleysols, Regosols, and Brunisols on fluvial landforms. Soil drainage is mostly moderately well to imperfectly drained, but varies from well to poorly drained. The wide range of moisture regime, soil drainage and soil taxa suggests a fluctuating water table in these sites.

Vegetation: *Salix glauca* (10-45%) is the dominant shrub with lesser amounts of *Betula glandulosa* (5-15%) and *Potentilla fruticosa* (5-20%) (Table 69). *Salix farrae* and *Salix barrattiana* also occur with low cover. Total shrub cover is 30 to 80%. The dense herb-dwarf shrub layer (60-90%) is dominated by *Danthonia intermedia* (10-40%) (Plate 59). Other important species are *Fragaria virginiana* (5-20%), *Phleum alpinum* (1-5%), *Trisetum spicatum* (1-3%), *Potentilla diversifolia* (1-3%), *Achillea millefolium* (1-2%), and *Valeriana sitchensis* (1%). Common species with <1% cover include *Epilobium angustifolium*, *Poa alpina*, *Carex* spp. (especially *Carex scirpoidea*), *Polygonum viviparum*, *Sibbaldia procumbens*, and *Aster ciliolatus*. Herbs are much more important than dwarf shrubs and species richness is high. Bryoid cover is variable but usually <30%. Species occurrence also varies, but the mosses *Tortula ruralis*, *Aulacomnium palustre*, *Polytrichum juniperinum*, and *Tortula norvegica* are most common. Lichen cover is usually <1%.

The S11 v.t. is mature successionally.

The S11 v.t. is distinguished from other v.t.s in which *Salix glauca* is important, primarily by the dominance of *Danthonia intermedia* in the herb-dwarf shrub layer. In S1, *Betula glandulosa* is usually dominant and the dense bryoid layer is dominated by *Tomenthypnum nitens*. The herb-dwarf shrub layer in S4 is dominated by *Erigeron peregrinus* and contains little, if any, *Danthonia intermedia*. *Kobresia myosuroides* is the dominant herb in S9, although intergrades between S9 and S11 occur. S10 occurs on steeper, drier sites than S11, as evidenced by the lack of gleyed soils and frequent dominance of *Arctostaphylos uva-ursi* in the herb-dwarf shrub layer. *Elymus innovatus* is the dominant herb in S12, although the two v.t.s have many other features in common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other Studies: A similar type (*Salix glauca*) was described by Ogilvie (1976) for the Alberta Rocky Mountains.

S12: *Salix glauca/Elymus innovatus*

(willow/hairy wild rye)

Environment: The S12 v.t. occurs on mesic to subhygric, Lower to Upper Subalpine sites (1800-2300 m B; 1500-2050 m J) on various slopes of mostly southerly and westerly aspect. The soils are well to imperfectly drained Orthic Eutric Brunisols, Regosols, and Humic Regosols. The landforms are predominantly fluvial, with some colluvial and morainal landforms.

Vegetation: *Salix glauca* (30-60%) is the dominant shrub with lesser amounts of *Betula glandulosa* (5-15%) and other *Salix* spp. (Table 70). Total shrub cover is 30 to 75% (Plate 60). *Elymus innovatus* (20-40%) dominates the herb-dwarf shrub layer. Total layer cover is 40 to 90% with herbs much more important than dwarf shrubs. Other common species, generally with 1 to 3% cover, include *Fragaria virginiana*, *Achillea millefolium*, *Astragalus alpinus*, *Delphinium glaucum*, *Epilobium angustifolium*, *Potentilla diversifolia*, *Equisetum scirpoides*, and *Poa* spp.. Bryoid cover is low (<25%) with *Tortula ruralis*, *Tortula norvegica*, *Cladonia pyxidata*, *Peltigera rufescens*, and *Ceratodon purpureus* most common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The S12 v.t. is mature successionally. Occasional stands contain scattered trees (<5% cover) but succession to forest appears unlikely.

The S12 v.t. is differentiated from the similar S4 by having >10% cover of *Elymus innovatus*, by the absence or low cover of *Salix barrattiana*, and by lower cover of *Betula glandulosa*. S10 is drier than S12, being typically mesic to subxeric, well to rapidly drained, without gleyed soils and frequently containing *Arctostaphylos uva-ursi*. *Salix barrattiana* dominance separates S8 from S12. Intergrades between S12 and S4, S8 or S10 occur.

Other Studies: In Banff, a similar type has been described by Beder (1967, *Salix glauca*). Hettinger (1975, *Salix glauca/Elymus innovatus*) and Crack (1977, *Salix glauca*) have described similar types in Jasper.

L1: *Potentilla fruticosa/Arctostaphylos uva-ursi-Galium boreale*

(shrubby cinquefoil / bearberry-northern bedstraw)

Environment: The L1 v.t. occurs on subxeric to xeric, Montane to Lower Subalpine (1050 - 2170 m) steeply sloping sites of southerly exposure in Banff and Jasper. The soils are rapidly to well drained Orthic and Orthic Humic Regosols developed on colluvial, eolian and glacial landforms.

Vegetation: *Potentilla fruticosa* is the dominant shrub with generally <15% (Table 71) cover. *Juniperus communis* (<5%) is also usually present with total shrub cover generally <15% (Plate 61). The herb-dwarf shrub layer is well developed with cover 25 to 80%. *Arctostaphylos uva-ursi* (10-55%) is dominant with lesser amounts of *Galium boreale* (<3%), *Artemisia frigida* (<5%), *Anemone multifida* (<2%), *Koeleria cristata* (<5%), *Elymus innovatus* (<15%), and *Campanula rotundifolia* (<1%). *Agropyron spicatum* (<10%) occurs in some Banff stands. The bryoid layer has cover usually <1%.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally, L1 is mature, its treeless character being maintained by droughty, unstable soils.

On more stable slopes where forest cover is greater, stands transitional to C3 may occur. The L1 v.t. is distinguished from H14 by

having abundant *Potentilla fruticosa* and *Juniperus communis* and lesser amounts of *Elymus* and *Koeleria*. Stands transitional between L1 and H14 occur.

Other Studies: Similar types have been described by Douglas (1974) for the southern Yukon (*Juniperus communis-Arctostaphylos uva-ursi*), in Jasper by Hettinger (1975, *Arctostaphylos uva-ursi-Calamagrostis purpurascens*), and Kuchar (1972, dry shrubby slope). The "steep herb-covered slopes" described by Jeffrey et al. (1968) in southwestern Alberta are also similar.

L2: *Juniperus communis-Salix glauca*

(juniper-willow)

Environment: The L2 v.t. occurs on subxeric, mostly Upper Subalpine sites (1900-2250 m) on steep slopes of southerly aspect. The soils are rapidly to well drained Orthic Regosols, Humic Regosols and Eutric Brunisols on colluvial landforms. The sites are commonly snow avalanched.

Tortula ruralis	--	--	--	--	--	--	--	.5	--	.5

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The shrub layer (Plate 62) is moderately dense (20-40%) and dominated by *Juniperus communis* (10-25%) and *Salix glauca* (10-25%). *Potentilla fruticosa*, *Rosa acicularis*, and *Shepherdia canadensis* also occur frequently (Table 72). The herb-dwarf shrub layer has a total cover of 40 to 80% with *Arctostaphylos uva-ursi* (10-25%) dominant. Other important species with 1 to 3% cover, are *Fragaria virginiana*, *Elymus innovatus*, and *Epilobium angustifolium*. *Achillea millefolium*, *Saxifraga bronchialis*, *Trisetum spicatum*, *Zygadenus elegans*, and *Linnaea borealis* occur frequently but with low cover. Bryoid cover is low (<10%) and sporadic.

Occasional trees of *Picea engelmannii* and regeneration of *Picea engelmannii* and *Abies lasiocarpa* occur in L2 stands, but avalanche activity appears to prevent development of a forest. Thus, L2 is regarded as mature successionally.

The L2 v.t. has similarities to S10 but is separated by the dominance in L2 of *Juniperus communis* and lesser cover values of *Betula glandulosa* and *Potentilla fruticosa*. Intergrades between the two v.t.s occur.

Other Studies: Kuchar (1978) described a similar type (deciduous avalanche scrub) in Yoho National Park, British Columbia.

L4: *Cassiope tetragona-Dryas octopetala-Salix nivalis*

(white mountain heather-mountain avens-snow willow)

Environment: The L4 tundra occurs on mesic to subhygric, predominantly Alpine (2040-2460 m J, 2160-2460 m B) gently to steeply sloping sites of predominantly northerly aspect throughout Banff and Jasper. Soils are well to moderately well drained Eutric and Dystric Brunisols, Melanic and Sombric Brunisols and Regosols, developed on morainal and colluvial landforms.

Vegetation: Trees are absent (Plate 63) except for occasional *Picea engelmannii* and *Abies lasiocarpa* krummholz and tree islands at the lower elevational limit. Shrubs are usually absent. Total heather cover is 10 to 50% with lesser amounts of *Phyllodoce glanduliflora* (<15%) and occasionally *Phyllodoce empetriformis* (Table 73). *Dryas octopetala* (10-35%) and *Salix nivalis* (<45%) are codominant and lesser amounts of *Polygonum viviparum* (<1%), *Potentilla diversifolia* (1%), *Silene acaulis* (<5%), *Castilleja occidentalis* (<1%), and *Salix arctica* (<15%) are present. Total herb-dwarf shrub cover is 25 to 85%. The bryoid layer has low to moderate cover (10-40%) with much of the cover attributable to species with sporadic occurrence. Characteristic species are *Dicranum scoparium* (<2%), *Cetraria islandica* (<5%),

Cetraria nivalis (<3%), other *Cetraria* species, and *Stereocaulon alpinum* (<3%).

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The L4 v.t. is successionally mature.

The L4 v.t. is distinguished by the dominance of *Cassiope tetragona* and occurs in association with H1, in depressions with greater snow accumulation than the more wind swept H1. Areas of transition to L5 may occur in snow accumulation areas where *Phyllodoce glanduliflora* and *Cassiope mertensiana* replace *Cassiope tetragona*. Stands which are transitional to O10 or C23 occur near the lower elevational limit.

Other Studies: Similar types have been described for Alberta by Mortimer (1978) for the northern Front Ranges *(Dryas integrifolia-Cassiope tetragona, Cassiope tetragona-Dryas octopetala)*, Ogilvie (1976) in the Alberta Rockies, and for the Kananaskis area, Trottier (1972), Jacques and Legge (1974), and Kondla (1978, Cassiope heath). Similar types in Jasper have been described by Hrapko and La Roi (1978, *Cassiope tetragona-Dryas octopetala*), Kuchar (1975, *Cassiope tetragona/Dryas octopetala*), La Roi (1975, *Cassiope tetragona/Dryas octopetala/Cetraria islandica*), and Crack (1977, *Cassiope tetragona*). In Banff, similar types have been described by Broad (1973, *Cassiope mertensiana*), Knapik et al. (1973, *Cassiope tetragona*), and Beder (1967, *Cassiope tetragona*). Kuchar (1978) described similar vegetation for Yoho National Park (four-angled mountain heather-white dryad heath tundra), and Choate and Habeck (1967) described similar vegetation at Logan Pass, Glacier National Park, Montana.

L5: ***Phyllodoce glanduliflora-Cassiope mertensiana-Antennaria lanata***

(heather-everlasting)

Environment: The L5 heather tundra occurs on mesic predominantly Alpine (2000-2380 m J, 2130-2530 m B), level to steeply sloping sites of various aspects in western Banff and Jasper. Soils are well to moderately well drained Eutric and Dystric Brunisols, Orthic Humo-Ferric Podzols, and Melanic and Sombric Brunisols developed on morainal and residual landforms.

Vegetation: Trees are absent (Plate 64) except for occasional *Picea engelmannii* and *Abies lasiocarpa* krummholz and tree islands at the lower elevational limits. Total heath cover is 20 to 75%, dominated by *Phyllodoce glanduliflora* (10-50%) and *Cassiope mertensiana* (10-70%) with lesser amounts of *Phyllodoce empetriformis* (<30%) and *Cassiope tetragona* (<10%) (Table 74). Other characteristic species include *Antennaria lanata* (2-15%), *Salix arctica* (<15%), *Sibbaldia procumbens* (<5%), *Potentilla diversifolia* (<1%), *Erigeron peregrinus* (<2%), *Luzula wahlenbergii* (1%), and in Jasper, *Artemisia norvegica* (<5%). Cover of the herb-dwarf shrub layer is 40 to 90%. Bryoid cover however, is generally low (<25%), the most abundant mosses being *Dicranum scoparium* (<10%) and *Polytrichum juniperinum* (<3%) with total moss cover 5 to 25%. Lichen cover is also low (<10%) with common species being *Cladonia ecmocyna* (<3%) and *Cetraria islandica* (<2%).

The L5 v.t. is successionally mature.

Some stands may be transitional to L4 where *Cassiope tetragona* and *Dryas octopetala* replace *Phyllodoce glanduliflora* and *Cassiope mertensiana*. Stands also occur which are transitional to C23 and O10 where trees are at their upper elevational limits.

Other Studies: Numerous other workers have described types similar to L5. In Banff, similar types have been described by Trottier and Scotter (1973, *Phyllodoce* types), Broad (1973, *Phyllodoce*), Knapik et al. (1973, *Phyllodoce glanduliflora, Antennaria lanata*), and Beder (1967, *Phyllodoce glanduliflora-Vaccinium scoparium*). In Jasper, similar types have been described by Crack (1977, *Phyllodoce glanduliflora*), Hrapko and La Roi (1978, *Cassiope mertensiana-Phyllodoce glanduliflora*), Kuchar (1975, *Phyllodoce glanduliflora-Cassiope mertensiana*), and La Roi (1975, *Abies lasiocarpa/Cassiope mertensiana/Pseudoleskea radicosa*). Elsewhere in Alberta, Ogilvie (1976, *Phyllodoce*), Kondla (1978, everlasting-phyllodoce), Kirby and Ogilvie (1969, *Phyllodoce*), Mortimer (1978, *Phyllodoce glanduliflora-Cassiope mertensiana*), Jacques and Legge (1974, yellow heather), and Trottier (1972, *Phyllodoce*) have described similar types. In British Columbia, similar types have been described by Knapik and Landals (1974, *Cassiope mertensiana*) in Mount Revelstoke National Park and by Kuchar (1978, mountain heather tundra) in Yoho National Park.

L6: *Juniperus horizontalis-Agropyron dasystachyum-Carex scirpoidea*

(creeping juniper-northern wheatgrass-sedge)

Environment: The L6 shrubby grasslands occur on subxeric Montane (1010-1050 m), gently to moderately steeply sloping sites of generally southerly aspect in the Talbot Lake and east gate area of Jasper. Soils are rapidly to well drained, extremely calcareous, Orthic Regosols developed on eolian landforms.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The herb-dwarf shrub layer (Plate 65) has cover of 50 to 70% and is dominated by *Juniperus horizontalis* (20-30%) with lesser amounts of *Agropyron dasystachyum* (5-10%) and *Carex scirpoidea* (5-30%) (Table 75). Other species commonly present are *Potentilla fruticosa* (<5%), *Hedysarum mackenzii* (<5%), *Koeleria cristata* (<5%), *Arctostaphylos uva-ursi* (<5%), *Senecio cymbalarioides* (<1%), and *Carex richardsonii* (<1%). *Stipa comata* may occur locally. The bryoid layer has very low cover (<1%) with no dominants evident.

The L6 v.t. is successionally mature.

The L6 v.t. is distinguished from other v.t.s by the dominance of *Juniperus horizontalis* and the dry environment characterized by Regosolic, eolian soils. The L6 v.t. often occurs in association with dense *Picea glauca* thickets which occur in mesic depressions between the sand dunes on which the L6 v.t. usually occurs. The L6 v.t. also occurs in association with H6 and transitional stands may occur on sites with low *Juniperus horizontalis* cover. Stands with abundant *Agropyron dasystachyum* may be transitional to H7.

Other Studies: Descriptions of similar types by other authors were not found.

L7: *Salix arctica-Potentilla diversifolia*

(arctic willow-cinquefoil)

Environment: The L7 v.t. occurs on mesic to subhygric, Upper Subalpine to Alpine sites (2200-2440 m B; 1980-2390 m J) on various slopes and aspects. A variety of soils including Regosols, Humic Regosols, Dystric Brunisols, Gleysols, Orthic Sombric Brunisols, and Orthic Humo-Ferric Podzols occur. Drainage ranges from well to imperfect and the landforms are primarily morainal and fluvial. The L7 v.t. occurs in deep snow accumulation areas and often receives seepage much of the growing season.

Vegetation: The L7 v.t. is dominated by dwarf shrubs and herbs (Plate 66) including *Salix arctica* (10-35%), *Antennaria lanata* (5-20%), and *Potentilla diversifolia* (1-3%) (Table 76). Other important species include *Salix nivalis* (1-5%), *Phyllodoce glanduliflora* (1-5%), and *Castilleja occidentalis* (1-3%). *Erigeron peregrinus*, *Poa alpina*, *Polygonum viviparum*, *Sibbaldia procumbens*, and *Artemisia norvegica* (in Jasper) occur frequently but with low cover. Total herb-dwarf shrub layer cover is usually 50 to 80%. This v.t. is species rich with a stand often containing 20 to 30 vascular species. Bryoid layer cover varies greatly (10-85%). Lichens are generally more important than bryophytes. Leading species include *Cladonia pyxidata*, *Cetraria ericetorum*, *Cetraria cucullata*, *Peltigera aphthosa*, *Stereocaulon alpinum*, and *Polytrichum juniperinum*.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The L7 v.t. is mature successionally.

The L7 v.t. is similar to H16 with many characteristic species in common. However, L7 is dominated by *Salix arctica* and the H16 dominants *Valeriana sitchensis*, *Trollius albiflorus*, and *Anemone occidentalis* are generally absent or with low cover in L7. The H2 v.t. also occurs in snow accumulation areas but meltout appears to occur later in H2. *Carex nigricans* is dominant in H2.

Other Studies: In Banff, Beder (1967, *Salix arctica-Carex*) has described a similar type. In Jasper, similar types have been described by Crack (1977, *Salix arctica*) and Hrapko and La Roi (1978, *Salix arctica-Antennaria lanata*, *Salix arctica-Arctagrostis arundinacea*). In other parts of Alberta, similar types have been described by Mortimer (1978, *Salix arctica-Salix nivalis*), Jacques and Legge (1974, dwarf arctic willow), Trottier (1972, *Salix arctica*), Ogilvie (1976, *Salix nivalis-Salix arctica*), and Kondla (1978, valeriana-anemone-willow). A similar type has been described from Yoho National Park in British Columbia by Kuchar (1978, variegated horsetail/arctic willow/moss meadow).

H1: *Dryas octopetala-Salix nivalis-Silene acaulis*

(mountain avens-snow willow-moss campion)

Environment: The H1 v.t. occurs on mesic to

subxeric, Alpine sites (2300-2550 m B, 2150-2400 m J) on various slopes and most frequently on southerly and westerly aspects. The soils are well drained Orthic Regosols, Orthic Humic Regosols, and Orthic Melanic, Orthic Sombric and Orthic Eutric Brunisols. Turbic and lithic soil phases are common. The landforms are predominantly morainal and colluvial. Solifluction is common.

Vegetation: The H1 tundra (Plate 67) has total herb-dwarf shrub cover of 20 to 50% with *Dryas octopetala* var. *hookeriana* (20-50%), *Salix nivalis* (1-10%), and *Silene acaulis* (1-3%) dominant (Table 77). In some Front Range sites in eastern and northern Jasper, *Dryas integrifolia* replaces *Dryas octopetala*. Other common species are *Oxytropis podocarpa* (<1-3%) and *Polygonum viviparum* (1-2%). Species with low cover but high frequency include *Selaginella densa*, *Potentilla diversifolia*, *Poa alpina*, *Salix arctica*, *Carex nardina*, *Castilleja occidentalis*, *Saxifraga oppositifolia*, *Trisetum spicatum*, and *Potentilla nivea*. Bryoid cover is generally <20% with the lichens *Cetraria nivalis*, *Cetraria cucullata*, *Cetraria ericetorum*, *Cetraria tilesii*, and *Thamnolia subuliformis* most common. H1 occupies wind-swept sites with low winter snow cover and often forms a pattern in the landscape with L5, L4, L7, and H2 occupying progressively deeper snow lie areas.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The H1 v.t. is successionally mature.

The H1 v.t. is characterized by the dominance of *Dryas octopetala* var. *hookeriana*. In the intricate, fine-scaled patterning of Alpine v.t.s, intergrades with L4 and L5 are common. The O19 v.t. differs by having usually >10% tree cover. The H4 v.t. has much greater amounts of *Kobresia myosuroides* and *Arctostaphylos uva-ursi* than H1.

Other Studies: Similar types were described for Alberta by Mortimer (1978) in the northern Front Ranges (*Dryas integrifolia-Oxytropis podocarpa*), Jeffrey et al. (1968) in the upper Oldman River drainage (alpine tundra), Ogilvie (1976, *Dryas hookeriana*), and See and Bliss (1980) in northern Front Ranges (*Dryas integrifolia-Oxytropis podocarpa-Salix nivalis*). In the Kananaskis area of Alberta, comparable types were described by Kirby and Ogilvie (1969, *Dryas*), Jacques and Legge (1974, *Dryas octopetala*), Kondla (1978, mountain avens) and Trottier (1972, *Dryas octopetala*). In Jasper, similar types were described by Hettinger (1975, *Dryas octopetala-Oxytropis campestris*), Hrapko and La Roi (1978, *Dryas octopetala-Oxytropis podocarpa*, *Dryas octopetala-Festuca brachyphylla*, *Dryas octopetala-Salix nivalis*), La Roi (1975, *Dryas octopetala/Salix nivalis/Polytrichum piliferum/Rhizocarpon geographicum*, *Dryas octopetala/Salix nivalis/Rhacomitrium lanuginosum/Rhizocarpon geographicum*), Kuchar (1975, *Dryas octopetala*/lichen, *Dryas octopetala/Polytrichum piliferum*), and Crack (1977, *Dryas octopetala*). In Banff, similar vegetation was recognized by Broad (1973, *Dryas octopetala-Empetrum nigrum*), Trottier and Scotter (1973, *Dryas octopetala*, *Salix nivalis*), Beder (1967, *Dryas hookeriana-Oxytropis podocarpa-Cetraria cucullata-Cetraria nivalis*), and Knapik et al. (1973, *Dryas hookeriana*, *Dryas hookeriana-Carex scirpoidea*). In Waterton Lakes National Park, the *Dryas* tundra described by Kuchar (1973) is analogous. In northeastern British Columbia, Raup (1934) described similar vegetation in the Mt. Selwyn area and Kuchar (1978) described white dryad tundra in Yoho National Park. Similar Alpine types extend south to Montana as described by Bamberg and Major (1968), Choate and Habeck (1967) on fellfields in Glacier National Park, Montana, and Johnson and Billings (1962, *Dryas octopetala*) in southern Montana.

H2: *Carex nigricans-Antennaria lanata*

(black alpine sedge-everlasting)

Environment: The H2 v.t. occurs on mesic to subhygric, predominantly Alpine (2050-2400 m J; 2180-2500 m B), gentle to steep sites on various aspects. Soils are predominantly moderately well drained Orthic Dystric and Orthic Sombric Brunisols, Orthic Humo-Ferric Podzols, and Regosols developed on morainal and residual landforms. Fluvial veneers are common.

Vegetation: Total cover of the herb-dwarf shrub layer is high (60-100%) (Plate 68) in large part due to *Carex nigricans* (10-90%) which usually forms a dense turf (Table 78).

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

Other characteristic herbs are *Antennaria lanata* (5-35%), *Luzula wahlenbergii* (<5%), *Sibbaldia procumbens* (<5%), *Veronica alpina* (<3%), and *Juncus drummondii* (<5%). On moister sites with later snow lie, *Ranunculus eschscholtzii* (<5%) is often present. *Poa alpina* (<10%) contributes significantly to total cover on some sites as do the dwarf shrubs *Salix arctica* (<12%) and *Phyllodoce glanduliflora* (<10%). The bryoid layer has low cover (<30%) and includes as characteristic species, *Pogonatum alpinum* (2-20%), *Tortula norvegica* (<2%), and *Cladonia ecmocyna* (<5%).

The H2 v.t. is successionally mature.

The H2 v.t. meadows are usually small and occur in areas of late snow lie and melt water runoff within larger areas of vegetation types such as L4, L5, and H1. The H2 v.t. often forms a pattern in the landscape with L7, L4, L5, and H1 occupying progressively shallower snow lie areas. The dominance of *Carex nigricans* readily separates this type from other v.t.s.

Other Studies: The H2 v.t. is a widespread v.t. and has been described by many workers. In Banff, Trottier and Scotter (1973, *Carex nigricans* types), Broad (1973, *Carex nigricans*), Beder (1967, *Carex nigricans*), and Knapik et al. (1973, *Carex nigricans*) have described similar types. Similar types have been described in Jasper by Kuchar (1975, *Carex nigricans*), Hrapko and La Roi (1978, *Carex nigricans-Luzula wahlenbergii*), and Crack (1977, *Carex nigricans*). Elsewhere in Alberta, similar types have been described by Ogilvie (1976, Kirby and Ogilvie 1969, *Carex nigricans*), Jacques and Legge (1974, black sedge), Trottier (1972, *Carex nigricans*), and Kondla (1978, alpine sedge-buttercup). In British Columbia, similar types have been described by Knapik and Landals (1974, *Carex nigricans*) in Mt. Revelstoke National Park and by Kuchar (1978, black alpine sedge types) in Yoho National Park.

H3: *Carex scirpoidea-Saxifraga aizoides*

(sedge-saxifrage)

Environment: The H3 v.t. occurs on hygric Montane to Lower Subalpine sites (1230-1970 m) on level fluvial landforms along river and lake shores. The soils are imperfectly to poorly drained Rego Gleysols. The sites are occasionally inundated and generally have high water tables due to adjacent water bodies.

Bryum spp.	--	--	--	--	05	--	.5

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The H3 v.t. is dominated by herbs (Plate 69) including *Carex scirpoidea* (1-5%), *Saxifraga aizoides* (1-5%), *Anemone parviflora* (1-3%), and *Tofieldia pusilla* (<3%) (Table 79). Common species with low cover include *Polygonum viviparum*, *Equisetum variegatum*, *Castilleja occidentalis*, *Dryas integrifolia*, *Arctostaphylos rubra*, and *Pinguicula vulgaris*. Scattered shrubs of *Potentilla fruticosa* and *Salix* spp. also occur

often. Total herb-dwarf shrub cover is usually 50 to 75%. Bryoid cover is generally <15% with unvegetated soil providing 30 to 50% cover.

The successional status of H3 is problematic. Periodic flooding and deposition appear to maintain some stands in this state for long periods. Other stands, perhaps less frequently disturbed, appear to increase in shrub cover and become S7. Thus, H3 can be characterized as early to intermediate successionally, with the successional development of some stands retarded by periodic disturbance.

The H3 v.t. can be distinguished from S7 by having sparse shrub cover and different herb-dwarf shrub layer dominants.

Other Studies: Descriptions of similar types by other authors were not found.

H4: *Dryas octopetala-Kobresia myosuroides-Arctostaphylos uva-ursi*

(mountain avens-kobresia-bearberry)

Environment: The H4 v.t. occurs on subxeric to mesic Upper Subalpine to Alpine (1750-2400 m J, 2000-2580 m B) sites of moderate to steep slope and southerly aspect, mostly in the Front Ranges of Banff and Jasper. The soils are generally well drained Orthic Melanic Brunisols, Orthic Eutric Brunisols, and Orthic Humic Regosols developed on morainal and colluvial landforms.

Vegetation: Tree and shrub cover is usually absent (Plate 70) although scattered krummholz *Abies lasiocarpa* and *Picea engelmannii* may be present. The herb-dwarf shrub layer has abundant cover (50-100%, Table 80) dominated by *Dryas octopetala* (10-35%), although *Dryas integrifolia* may substitute in some Front Range stands. Other plants usually present are *Kobresia myosuroides* (15-40%), *Arctostaphylos uva-ursi* (5-30%), *Polygonum viviparum* (<5%), *Androsace chamaejasme* (<3%), *Oxytropis podocarpa* (<15%), and *Silene acaulis* (<2%). *Elymus innovatus* is usually absent but may have cover up to 25%. The bryoid layer is dominated by lichens especially *Cetraria* spp., with *Cetraria nivalis* (<10%) and *Cetraria cucullata* (<10%) being dominant. Moss cover is sparse (<5%) with total bryoid cover being 0 to 30%.

Successionally H4 is mature.

The H4 v.t. is distinguished from H1 by usually having abundant *Kobresia myosuroides* and *Arctostaphylos uva-ursi* and by the generally steep southerly aspects. The H4 v.t. is distinguished from H5 and H14 by the usually abundant *Kobresia* and *Arctostaphylos* and generally sparse *Elymus innovatus*. Intergrades with H14 occur.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other Studies: In Banff, Knapik et al. (1973, *Kobresia myosuroides*) have described a similar type. Similar types have been described in Jasper by Kuchar (1975, *Kobresia bellardii*), Crack (1977, *Kobresia myosuroides, Arctostaphylos uva-ursi*), and Hrapko and La Roi (1978, *Dryas octopetala-Kobresia bellardii*). In other parts of Alberta, Ogilvie (1976, Kirby and Ogilvie 1969, *Kobresia myosuroides*), Jacques and Legge (1974, kobresia), Trottier (1972, *Kobresia myosuroides*), and Johnson (1975, *Dryas integrifolia-Selaginella densa-Kobresia myosuroides, Arctostaphylos uva-ursi-Dryas integrifolia, Dryas integrifolia-Kobresia-Potentilla fruticosa*) have described similar types. Bamberg and Major (1968) have described similar stands from the Big Snowy Mountains of central Montana and in Glacier National Park, Montana.

H5: *Elymus innovatus-Fragaria virginiana-Epilobium angustifolium*

(hairy wild rye-wild strawberry-fireweed)

Environment: The H5 grasslands occur on generally mesic usually Upper Subalpine (1720-2000 m J, - 2270 m B) steeply sloping sites of southerly aspect. Soils are predominantly well drained Orthic Melanic Brunisols and Humic Regosols on colluvial landforms. Sites of H5 are subject to frequent snow avalanching.

Table 81 A stand representing the hairy wild rye-wild strawberry-fireweed (H5) v.t.

Tortula ruralis	--	--	--	--	.5	--	--	07	.5	.5 .5

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: Tree cover is absent (Plate 71) or limited to scattered individuals particularly towards the edges of the avalanche paths. Shrub cover is low (<10%), primarily *Salix* spp. and *Rosa acicularis* (<5%) (Table 81). The herb-dwarf shrub layer is dense (55-100%) and is dominated by *Elymus innovatus* (15-55%), *Fragaria virginiana* (1-10%), and *Epilobium angustifolium* (<10%). Other characteristic species are *Achillea millefolium* (<5%), *Myosotis alpestris* (<10%) *Potentilla diversifolia* (<1%), and *Zygadenus elegans* (<8%). The bryoid layer has sparse cover (<5%).

Successionally, H5 is mature, the herbaceous physiognomy being maintained by frequent avalanches.

The H5 v.t. is distinguished from other grassland types (H6,H7,H13) by the dominance of *Elymus innovatus* and a much higher elevation, and from H14 by being more mesic and lacking or having in low abundance characteristic H14 species such as *Koeleria cristata*, *Hedysarum* spp. and *Bromus pumpellianus*. H5 is distinguished from H4 by the absence of *Dryas octopetala* and *Kobresia myosuroides* and the presence of moister site conditions with lower elevations. Moist stands with abundant *Erigeron peregrinus* and *Valeriana sitchensis* may be transitional to H16. Stands with abundant *Salix* or *Abies lasiocarpa* may be transitional to S2.

Other Studies: In Alberta, similar types have been described only from the Front Ranges of the Rocky Mountains. Kirby and Ogilvie (1969) described a similar "seepage avalanche meadow type" and similar vegetation was described by Mortimer (1978, *Elymus innovatus-Mertensia paniculata*), Jacques and Legge (1974) in the Kananaskis area (*Elymus innovatus*), Kondla (1978, herb avalanche track) in the Kananaskis area, and Trottier (1972) in the Highwood Pass area (*Thalictrum occidentale*).

H6: *Koeleria cristata-Artemisia frigida-Linum lewisii*

(junegrass-pasture sage-wild blue flax)

Environment: The H6 grasslands occur on subxeric to xeric Montane (1250-1620 m B, 1000-1140 m J), level to moderately sloping sites of level to southerly aspect. Soils are rapidly to well drained Orthic Regosols, Humic Regosols, and Orthic Eutric Brunisols developed on fluvial, eolian, and glaciofluvial landforms.

Vegetation: *Koeleria cristata* (15-30%) is the dominant plant; its cover can vary widely between years depending upon summer precipitation (Table 82). Other characteristic species are *Artemisia frigida* (1-20%), *Linum lewisii* (1-10%), *Antennaria nitida* (1-10%), *Senecio cymbalarioides* (1-5%), *Galium boreale* (<5%), and *Gaillardia aristata* (<5%).

Herb-dwarf shrub layer cover is 25 to 90% (Plate 72). Cover of the bryoid layer is <3% with *Tortula ruralis* the most frequently occurring moss.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

The H6 v.t. is successionally mature, but it appears that in areas such as near Henry House in Jasper, that the lodgepole pine/juniper/bearberry v.t. (C3) may be encroaching upon the grasslands.

The H6 v.t. is distinguished from H13 and H7 by the dominance of *Koeleria cristata* rather than by *Stipa richardsonii* and *Agropyron dasystachyum* respectively. The dominance in H14 of *Elymus innovatus* and Subalpine elevations distinguish it from H6.

Other Studies: Similar types have been described from Banff and Jasper by Stringer (1973, *Koeleria-Calamagrostis montanensis*, *Koeleria-Geum triflorum*) and from Jasper by La Roi (1975, *Koeleria cristata/Antennaria nitida/Bryum caespiticium*).

H7: ***Agropyron dasystachyum-Artemisia frigida***

(wheatgrass-pasture sage)

Environment: The H7 grasslands occur on xeric Montane (1540-1640 m B, 1040-1300 m J) generally steeply sloping sites of southerly aspect. Soils are rapidly to well drained Orthic Eutric Brunisols and Orthic Regosols developed on colluvial, glacial, and fluvial landforms.

Vegetation: Herb-dwarf shrub cover is usually 20 to 50% (Plate 73) and dominated by *Agropyron dasystachyum* (5-50%) with lesser amounts of *Artemisia frigida* (1-10%), *Koeleria cristata* (2-10%), and *Achillea millefolium* (<5%) (Table 83). Moss and lichen cover is negligible in most stands with total cover generally <1% while bare mineral soil is often up to 50% of the ground surface.

Table 83 Stands representing the wheatgrass-pasture sage (H7) v.t.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

The H7 v.t. is successionally mature.

The H7 v.t. is distinguished from all other grasslands by the dominance of *Agropyron dasystachyum*, but stands with abundant *Koeleria cristata* may be transitional to H6. The absence of *Stipa richardsonii* and the presence of usually steep slopes in H7 distinguish this v.t. from H13. The dominance in H14 of *Elymus innovatus* and Subalpine elevations distinguish it from H7.

Other Studies: A similar type was described by La Roi (1975, *Agropyron dasystachyum/Artemisia frigida*) for Jasper.

H8: ***Dryas drummondii-Epilobium latifolium***

(yellow dryad-willow herb)

Environment: The H8 v.t. occurs on subxeric to subhygric Montane to Lower Subalpine

(1000-1700 m) sites of usually gentle slopes on various aspects. The soils are usually rapidly, but may be imperfectly, drained Orthic Regosols and Orthic Humic Regosols developed on recent fluvial, glaciofluvial and morainal landforms.

Vegetation: Tree cover is usually limited to scattered *Picea glauca* and *Picea engelmannii* with occasional representatives of other species although trees are often absent (Table 84). Shrub cover is generally low (<15%) but may be greater on moist sites. Usual species are *Shepherdia canadensis* (<10%), *Salix brachycarpa* (<15%), and other *Salix* spp.. The herb-dwarf shrub layer is species poor, dominated by *Dryas drummondii* with 25 to 80% cover (Plate 74). *Epilobium latifolium* (<2%) is the other characteristic species of this type and is usually found in moist depressions and near stream channels. *Arctostaphylos uva-ursi* (<5%) is often present in dry stands. The bryoid layer has low cover (<10%) with common representatives being *Drepanocladus uncinatus* (<3%) and *Tortula norvegica* (<10%).

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Successionally H8 is early and appears to be seral to O3.

The H8 v.t. is readily separable from other types by the dominance of *Dryas drummondii* and occurrence on recent landforms. Stands transitional to H3 and S7 occur in moist situations and to O3 on long-stabilized fluvial materials.

Other Studies: Heusser (1956) described a type similar to H8 for Banff and Jasper. Other similar types in British Columbia have been described by Kuchar (1978, yellow dryad) in Yoho National Park and by Raup (1934, *Dryas drummondii*) in northeastern British Columbia. In the Yukon Territory, Douglas (1974, *Dryas drummondii*) in Kluane National Park and Orloci and Stanek (1979, *Dryas drummondii*) have described similar types. Kershaw (1981, *Dryas drummondii*) described a similar type in Nahanni National Park.

H9: *Caltha leptosepala-Trollius albiflorus*

(mountain marigold-globeflower)

Environment: The H9 herb meadows occur on subhygric to hygric Upper Subalpine to Alpine (2330-2400 m B, 1880-2300 m J) gently to moderately sloping sites of northerly to easterly aspect. Soils are poorly drained Gleysols developed on fluvial and morainal landforms. H9 sites are usually depressional, in areas where snow melts late and seepage is received throughout the growing season.

Vegetation: Herb-dwarf shrub cover is high (70-100%, Plate 75) and is dominated by *Caltha leptosepala* (10-25%) and *Trollius albiflorus* (15-40%) with lesser amounts of *Senecio triangularis* (<10%), *Erigeron peregrinus* (<10%), *Carex nigricans* (5-20%), *Antennaria lanata* (<10%), *Salix arctica* (5-10%), *Pedicularis bracteosa* (<5%), *Polygonum viviparum* (<5%), and *Valeriana sitchensis* (<5%) (Table 85). Bryoid cover is 20 to 75% with the common dominants being *Aulacomnium palustre* (10-50%) and *Campylium stellatum* (<10%). *Drepanocladus uncinatus*, *Philontis fontana* and *Tomenthypnum nitens* may be locally abundant or dominant but are often absent.

The H9 v.t. is successionally mature.

The H9 v.t. is distinguished from all other v.t.s by the dominance of *Caltha leptosepala* and wet site conditions. Where water is free-standing for a large part of the growing season, stands may be transitional to H10. Where the site is not as wet as the modal H9, the vegetation may be transitional to H16 or H2. H9 meadows are usually small in extent and generally occur within areas of L4, L5, and H1.

Other Studies: Similar types were described by Kuchar (1975) in Jasper (*Artemisia nor-*

vegica/Salix arctica), Broad (1973) at Bow Summit in Banff (*Trollius albiflorus-Caltha leptosepala*), and Trottier and Scotter (1973) in Banff (*Carex/Caltha leptosepala/Sphagnum*).

H10: ***Eriophorum angustifolium/Drepanocladus*** **spp.**

(cottongrass/moss)

Environment: The H10 fens occur on hydric Upper Subalpine (1970-2220 m) level to very gently sloping (<5%) sites on various aspects at the Upper Subalpine to Alpine boundary. Soils are poorly to very poorly drained Rego Gleysols and Terric Mesisols developed on fluvial landforms and to a lesser extent on morainal landforms with fluvial veneers. H10 sites are usually depressional areas where snow melts late and seepage is received throughout the growing season.

Vegetation: Cover of the herb-dwarf shrub layer (Plate 76) is moderate to high (20-60%) most of which is attributable to *Eriophorum angustifolium* (Table 86). Toward the edges of this v.t. where free standing water is less abundant, species such as *Caltha leptosepala*, *Carex nigricans*, *Pedicularis groenlandica*, and *Scirpus caespitosus* may occur with varying cover. The often submerged bryoid layer has generally high cover (70-80%) dominated by *Drepanocladus exannulatus* and *Drepanocladus revolvens*. Other mosses with often high cover are *Paludella squarrosa* and *Calliergon sarmentosum*.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

The H10 v.t. is successionally mature.

The H10 v.t. is distinguished from other v.t.s by the dominance of *Eriophorum angustifolium* and site conditions characterized by standing or slowly flowing water during the growing season. Toward the periphery, where conditions are less wet, a gradient from H10 to H9 to H16 may occur as soil drainage improves. The H10 meadows are small in extent and occur in depressions within larger areas of O10, O9, and S8 vegetation.

Other Studies: In Banff, similar types have been described by Trottier and Scotter (1973, *Eriophorum* spp.-*Carex aquatilis*) and Knapik et al. (1973, *Carex eleusinoides-Eriophorum scheuchzeri-Eriophorum angustifolium*). In Jasper, Kuchar (1975, *Eriophorum polystachion/Calliergon sarmentosum*) described a similar type. In British Columbia, Knapik and Landals (1974) described an *Eriophorum polystachion* type in Mount Revelstoke National Park and Kuchar (1978) described a similar cottongrass meadow in Yoho National Park.

H11: *Carex aquatilis-Carex rostrata*

(water sedge-beaked sedge)

Environment: The H11 fens occur on hydric to subhydric Montane to Upper Subalpine (1380-2220 m B, 1220-1880 m J) and occasionally Alpine (2290 m B) sites, in predominantly level situations. Soils are very poorly drained Terric Mesisols and Rego Gleysols developed on fluvial and to a lesser extent on morainal landforms.

Vegetation: Cover of the herb-dwarf shrub layer is high (50-85%, Plate 77) almost entirely *Carex aquatilis* (15-70%) and *Carex rostrata* (10-60%) (Table 87). *Carex physocarpa* can be dominant in some high elevation stands. *Equisetum fluviatile* may have high cover (20-55%) in some low elevation stands where water is slowly flowing. Aquatic plants such as *Lemna minor* and *Utricularia* spp. may be present but this v.t. is generally very species poor. Bryoid cover is moderate to high (50-85%) but can be quite variable among stands due to differences in moisture regime and flooding frequency. Species commonly represented are *Drepanocladus revolvens* (10-55%), *Tomenthypnum nitens* (up to 35% on hygric sites), *Campylium stellatum* (<15%), and *Bryum pseudotriquetrum* (<10%).

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The H11 v.t. is successionally mature and is relatively stable. There is however the tendency for peat to accumulate over a period of several hundred years with the subsequent invasion of shrubs and trees.

The H11 v.t. is distinguished from other wet fen v.t.s by the dominance of the large sedges *Carex aquatilis* and *Carex rostrata*. Toward the periphery on higher, better drained sections, transitions to wet shrub types such as S1 and S7 may occur. The H11 v.t. seldom covers large areas away from floodplains where it may be extensive.

Other Studies: Similar types have been described from the southern Yukon (Orloci and Stanek 1979, *Carex-Equisetum*), northeastern British Columbia (Raup 1934, *Carex rostrata*), northern Alberta (Lewis et al. 1928, *Carex aquatilis*), and southward along the Rocky Mountains. In Jasper, Kuchar (1972) described *Carex aquatilis* wet meadow in the Athabasca Valley and Crack (1977) described a *Carex aquatilis* type in Wilcox Pass. In the Kananaskis area, similar types were described by Kondla (1978, *Carex aquatilis* wetland), in Yoho National Park by Kuchar (1978, tall sedge meadow), and by Kuchar (1973) in Waterton Lakes National Park (sedge meadow).

H12: Saxicolous lichen

(saxicolous lichen)

Environment: The H12 v.t. occurs on subxeric to xeric Alpine sites (2400-2800 m) on various slopes and aspects. The soils are Orthic Regosols or nonsoil occurring on the Miscellaneous Landscapes Rockland (R) and Colluvial Rubble (CR).

Vegetation: The H12 v.t. is extremely sparsely vegetated (Plate 78). Total plant cover is commonly <20% with lichens contributing most cover (Table 88). Species usually have <1% cover. Common vascular plants are *Silene acaulis*, *Saxifraga oppositifolia*, *Selaginella densa*, *Oxytropis podocarpa*, *Draba incerta*, and *Salix nivalis*. All have a prostrate, cushion growth form. Important lichens include *Rhizocarpon geographicum*, *Xanthoria elegans*, *Sporastatia testudinea*, *Cetraria tilesii*, *Cetraria nivalis*, *Acarospora chlorophana*, *Cladonia pyxidata*, *Dactylina ramulosa*, *Lecanora melanophthalma*, *Rhizocarpon disporum*, *Umbilicaria virginis*, and *Thamnolia subuliformis*. A few mosses are sometimes present, including *Hypnum revolutum*, *Tortula ruralis*, and *Bryum* spp..

This v.t. is characteristic of weakly or noncalcareous sites and is mature successionally.

The H12 v.t. is distinguished by its very low plant cover, which is dominated by lichens

and occurrence at elevations above most other v.t.s.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other Studies: Beder (1967) described a similar type (ridge summit type) in Banff. In Jasper, similar types have been described by Crack (1977, high altitude open vegetation), Hettinger (1975, rock and lichen), Hrapko and La Roi (1978, *Potentilla nivea-Silene acaulis*), Kuchar (1975, cushion-rosette, lichen tundra), and La Roi (1975, *Silene acaulis/Alectoria*). Elsewhere in Alberta, similar types have been described by Ogilvie (1976, Kirby and Ogilvie 1969, stonefield-lichen), Jacques and Legge (1974, bare rock-lichen), Bryant and Scheinberg (1970), Kuchar (1973, saxicolous lichen tundra), and Kondla (1978, lichen dominated type). In British Columbia, Raup (1934) and, in Yoho National Park, Kuchar (1978, lichen tundra, boulder and rock tundra) have described similar types.

H13: *Stipa richardsonii-Koeleria cristata-Antennaria nitida*

(Richardson needlegrass-junegrass-everlasting)

Environment: The H13 grasslands occur on subxeric to xeric Montane (1250-1670 m), level to gently sloping sites of southerly aspect. Soils are rapidly to well drained Orthic Regosols and Orthic Eutric Brunisols developed on glaciofluvial, fluvial, colluvial, and glacial landforms.

Vegetation: *Stipa richardsonii* (5-20%) is the dominant plant (Table 89). *Koeleria cristata* is usually less abundant (2-10%). Other characteristic species are *Antennaria nitida* (<8%), *Anemone multifida* (<5%), *Selaginella densa* (5%), *Penstemon confertus* (<3%), and *Galium boreale* (<2%). *Festuca scabrella* is present in several Banff stands. Total cover of the herb-dwarf shrub layer is 65 to 100%, the majority being due to grasses (Plate 79). The bryoid layer is sparse, dominated by *Cetraria* spp. (<5%). H13 is often associated with scattered shrubs and as small areas within and bordering lodgepole pine (C3) and Douglas fir (C1) forests.

Successionally, H13 is mature.

The H13 v.t. is distinguished from H6 by the dominance of *Stipa richardsonii* rather than of *Koeleria cristata*.

Other Studies: Stringer (1973) described simi-

lar vegetation (*Stipa richardsonii* shrub savanna) in Banff and Jasper.

H14: *Elymus innovatus-Koeleria cristata-Arctostaphylos uva-ursi*

(hairy wild rye-junegrass-bearberry)

Environment: The H14 grasslands occur on subxeric Lower to Upper Subalpine (1600-2300 m B, 1800-2200 m J), steeply sloping sites of southerly aspect, mostly in the Front Ranges of eastern Banff and Jasper. Soils are rapidly to well drained Orthic Melanic and Orthic Eutric Brunisols, and Orthic Humic Regosols developed on colluvial and morainal landforms.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: Shrub cover is low (generally <5% but occasionally >15%) with *Potentilla fruticosa* and *Salix glauca* being the most frequent representatives. The herb-dwarf shrub layer (Plate 80) has high cover (60-100%) and is dominated by *Elymus innovatus* (5-50%), *Koeleria cristata* (5-35%), and *Arctostaphylos uva-ursi* (5-20%) (Table 90). *Hedysarum sulphurescens* (5-15%) is often abundant in Banff. Other species usually present are *Bromus pumpellianus* (1-10%), *Achillea millefolium* (1-2%), *Fragaria virginiana* (<10%), *Anemone multifida* (<10%), *Cerastium arvense* (<10%), *Oxytropis splendens* (1%), *Myosotis alpestris* (1-5%), *Antennaria nitida/rosea* (1-2%), *Campanula rotundifolia* (<3%), and *Poa cusickii/spp.* (<1-5%). The bryoid layer has low cover (<10%) and *Tortula ruralis* (<5%) is the dominant.

Successionally, H14 is mature.

The H14 v.t. is distinguished from H4 by the absence in the former of *Dryas octopetala*, the presence of much more *Elymus innovatus*, and by generally lower elevations. Stands transitional to H4 occur. The H14 v.t. is distinguished from H5 by more abundant *Koeleria cristata*, *Hedysarum* spp., *Bromus pumpellianus* and *Arctostaphylos uva-ursi* reflecting the generally drier conditions in H14. The higher elevations of H14 separate it from low elevation grasslands such as H6, H7, and H13. Stands with abundant *Potentilla fruticosa* and low grass cover are transitional to L1.

Other Studies: Similar types have been described in Banff and Jasper by Stringer (1973, *Elymus innovatus* shrub savanna) and Beder (1973, *Elymus innovatus*). Ogilvie (1976, Kirby and Ogilvie 1969, *Elymus innovatus*) has also described a similar type. In the Porcupine Hills, similar grasslands have been described by Ogilvie (1971).

H15: *Dryas integrifolia-Carex rupestris*

(mountain avens-curly sedge)

Environment: The H15 v.t. occurs on subhygric, Upper Subalpine (1900 m) steeply sloping (90%) slopes of easterly aspect in the Columbia Icefields area of Jasper on failed morainal landforms. Soils are Orthic Eutric Brunisols and Orthic Regosols. Nearly 40% of the ground surface is unvegetated.

Vegetation: *Dryas integrifolia* (10%) and *Carex rupestris* (20%) are the dominant plants (Table 91). Other characteristic species are *Carex scirpoidea* (3%), *Carex albo nigra* (3%), *Cassiope tetragona* (3%), *Ledum groenlandicum* (2%), and *Arctostaphylos rubra* (1%). Total vascular plant cover which is confined to the herb - dwarf shrub layer is <50%. The bryoid layer has low cover with traces of *Cetraria* spp..

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The H15 v.t. is successionally mature, its treeless character maintained by active soil creep.

The H15 v.t. appears to be very limited in extent, with only one plot sampled, but its similarity with some Front Range and subarctic communities make it worthy of note. It is not a significant component in any Ecosite, but is readily visible from Highway 93 about 1 km north of Athabasca Glacier on the west side of the Sunwapta River.

The H15 v.t. is distiguished from H1 by having abundant *Carex rupestris*, wetter site conditions, and steeper slopes.

Other Studies: In Alberta, *Dryas integrifolia-Carex rupestris* types have been described only from the Front Ranges of the Rocky Mountains by Mortimer (1978) and See and Bliss (1980). Bamberg and Major (1968) described a *Dryas integrifolia-Carex rupestris* dominated community in the Big Snowy Mountains of central Montana.

H16: *Erigeron peregrinus-Valeriana sitchensis*

(fleabane-valerian)

Environment: The H16 v.t. occurs on subhygric to mesic Upper Subalpine sites (1950-2350 m) on various slopes and aspects. The soils are imperfectly to well drained Dystric Brunisols, Gleysols, and Regosols on fluvial and morainal landforms.

Vegetation: The H16 v.t. is a species rich herb meadow (Plate 81). Total herb-dwarf shrub layer cover is 70 to 100% with *Erigeron peregrinus* (5-20%), *Valeriana sitchensis* (5-20%), *Trollius albiflorus* (5-20%), and *Anemone occidentalis* (5-15%) dominant (Table 92). Other important species are *Senecio triangularis* (1-10%), *Antennaria lanata* (1-5%), *Artemisia norvegica* (Jasper) (1-5%), *Pedicularis bracteosa* (<1-3%), *Salix arctica* (1-5%), and *Potentilla diversifolia* (<1-2%). Common species with low cover include *Carex nigricans*, *Sibbaldia procumbens*, *Phleum alpinum*, *Veronica alpina*, and *Poa alpina*. Bryoid cover is variable but usually <15% with the mosses *Pseudoleskea radicosa*, *Tortula ruralis*, *Aulacomnium palustre*, and *Bryum pseudotriquetrum* most common.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT

The H16 v.t. is mature successionally.

The H16 v.t. has many species in common with L7. The L7 v.t., however, is dominated by *Salix arctica* and the characteristic H16 species *Valeriana sitchensis*, *Trollius albiflorus*, and *Anemone occidentalis* are generally absent or with low cover in L7. The H2 v.t. differs in having *Carex nigricans* dominant.

Other Studies: In Banff, similar types have been described by Broad (1973, *Anemone occidentalis-Thalictrum occidentale*) and Trottier and Scotter (1973, *Senecio triangularis-Caltha leptosepala-Trollius albiflorus-Erigeron peregrinus, Anemone occidentalis-Valeriana sitchensis-Veratrum eschscholtzii*). Similar types have been described in Jasper by Kuchar (1975, *Artemisia norvegica/Salix arctica*) and La Roi (1975, *Valeriana sitchensis/Cassiope mertensiana/Orthocaulis floerkii*).

Elsewhere in Alberta, Jacques and Legge (1974, meadow rue), Trottier (1972, *Thalictrum occidentale*), and Kuchar (1973, moist forb meadow) have described similar types. In British Columbia, similar types have been described by Knapik and Landals (1974, *Valeriana sitchensis-Luzula glabrata*) in Mount Revelstoke National Park and by Kuchar (1978, moist forb meadow) in Yoho National Park. Choate and Habeck (1967) and Habeck (1969) described a similar type in Glacier National Park, Montana.

H19: *Agropyron spicatum-Elymus innovatus-Aster conspicuus*

(bluebunch wheatgrass-hairy wild rye-showy aster)

Environment: The H19 grasslands occur on xeric Montane to Lower Subalpine (1400-1700 m) moderately steep sites of southwest aspect in Banff. Soils are predominanty rapidly drained Orthic Regosols on colluvial and glacial landforms.

Table 93 Stands representing the bluebunch wheatgrass-hairy wild rye-showy aster (H19) v.t.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: Shrub cover is low and is confined to sporadic occurrences of *Juniperus communis* and *Rosa acicularis*. The dense (50-85%) herb-dwarf shrub layer is comprised of the dominants *Agropyron spicatum* (15-30%), *Elymus innovatus* (10-30%), and *Koeleria cristata* (3-10%) (Table 93). Other characteristic species include *Aster conspicuus* (3-5%), *Oxytropis splendens* (<8%), *Antennaria nitida/rosea* (<2%), and *Cerastium arvense* (<2%). The bryoid layer has very little or no cover, with no evident dominants.

Successionally H19 is mature, the community being maintained by the droughty southerly aspects. H19 is not a significant component in any Ecosite and appears to be very limited in extent, the three sampled plots occurring on slopes above Hillsdale meadow in Banff, but its similarity to more southerly grasslands makes it worthy of note.

The H19 v.t. is distinguished from other grassland v.t.s (H4, H5, H6, H7, H13, and H14) by the dominance of *Agropyron spicatum*, or codominance with *Elymus innovatus*. Stands with low *Agropyron* cover are transitional to H14.

Other Studies: A similar type was described in Montana by Mueggler and Stewart (1980, *Festuca scabrella/Agropyron spicatum*). *Elymus innovatus* in Banff substitutes for *Festuca scabrella* in Montana.

H20: *Saxifraga bronchialis-Elymus innovatus*

(spotted saxifrage-hairy wild rye)

Environment: The H20 v.t. occurs on subxeric to xeric, Upper Subalpine (1950-2200 m) sites on steep southerly slopes. The soils are rapidly to very rapidly drained Orthic Regosols on colluvial landforms.

Table 94 Stands representing the spotted saxifrage-hairy wild rye (H20) v.t.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Vegetation: The composition of H20 is heterogeneous. Common species include *Saxifraga bronchialis*, *Elymus innovatus*, *Potentilla nivea*, *Achillea millefolium*, *Festuca saximontana*, *Zygadenus elegans*, and *Tortula ruralis* (Table 94). Total vegetation cover is typically low (<50%) and patchy reflecting the harsh environmental conditions (Plate 185). In addition to being dry and having little soil development, many H20 stands are subject to snow avalanching.

The H20 v.t. is mature successionally.

The H20 v.t. is distinguished from H12 by having lower elevation, lower lichen cover, and greater vascular plant cover.

Other Studies: The "rock outcrop association" described by Kondla (1978) for the Kananaskis area is similar.

KEY TO VEGETATION TYPES
P.L. Achuff

USE OF THE KEY

The term "dominant" (species with the highest % cover) is used in the key, but "abundant" can usually be substituted. Occasionally, species other than those in the key leads may be dominant. In such cases, use the species in the key leads which is most abundant. For example, in a *Pinus contorta/Shepherdia canadensis* closed forest (lead 8) *Elymus innovatus* (35%) may be dominant with *Linnaea borealis* (5%), *Aster conspicuus* (2%) and *Vaccinium scoparium* (25%). *Elymus innovatus* is dominant but not in the key leads. Therefore, use the most abundant species which is in the leads, which is *Vaccinium scoparium* and the stand keys to C18.

The following general cover value terms are used but should not be rigidly interpreted: sparse <15%, moderate 15-50%, and dense >50%. Often the cover of a species relative to other species in the stand is a better guide to its significance than the absolute cover values. Polychotomous leads have been used to save space and simplify the key. Alternative leads are grouped to minimize confusion.

Not all stands will key to a v.t.; intermediates occur and heterogeneous stands may be virtually unclassifiable, although their affinities may be apparent. The descriptions contain additional information and comments on related v.t.s which will help better place the stand in question. The key is only an aid to classification. Always consult the v.t. description to validate the determination.

KEY TO PHYSIOGNOMIC GROUPS

1a. Vegetation with trees ≥ 5m tall and tree cover >5 % 2
1b. Vegetation without trees ≥5m tall or tree cover <5 % 3

9a. Herb-dwarf shrub layer sparse, bryoid layer well developed with *Hylocomium splendens* and *Pleurozium schreberi* dominant, site mesic C11

9b. Herb-dwarf shrub layer moderate to dense, sites mesic or subxeric 10

10a. *Vaccinium caespitosum* dominant dwarf shrub, *Cladonia* spp. <25%, site mesic to subxeric C9

10b. *Empetrum nigrum* dominant dwarf shrub, *Cladonia* spp. >25%, site subxeric C35

10c. *Juniperus communis* and *Arctostaphylos uva-ursi* dominant dwarf shrubs, site subxeric C3

11a. Herb-dwarf shrub layer dominated by *Equisetum* spp. 12

11b. Herb-dwarf shrub layer not dominated by *Equisetum* spp. 13

12a. Shrub layer dense, dominated by *Rosa acicularis*; *Arnica cordifolia*, *Elymus innovatus* and *Mertensia paniculata* usually absent, Montane, site subhygric to hygric, *Picea* usually *Picea glauca* C4

12b. Shrub layer sparse, *Rosa acicularis* usually absent; *Arnica cordifolia*, *Elymus innovatus* and *Mertensia paniculata* usually present, Lower Subalpine, site mesic to subhygric, *Picea* usually *Picea engelmannii* C32

13a. Shrub layer dominated by *Rosa acicularis*, Jasper only C27

13b. Shrub layer dominated by *Menziesia glabella* C14

13c. Shrub layer dominated by *Vaccinium membranaceum* (or *Rhododendron albiflorum*) C21

13d. Shrub layer dominated by *Salix vestita*, *Cassiope tetragona* present C24

13e. Shrub layer dominated by *Ledum groenlandicum*, *Empetrum nigrum* usually present C30

13f. Shrub layer dominated by *Shepherdia canadensis* 14

13g. Shrub layer sparse 15

14a. *Thuidium abietinum* dominant bryophyte C26

14b. *Hylocomium splendens* dominant bryophyte C37

15a. *Thuidium abietinum* dominant bryophyte, Jasper only C2

15b. *Thuidium abietinum* not dominant bryophyte, both Banff and Jasper 16

16a. *Vaccinium membranaceum* dominant dwarf shrub, *Barbilophozia lycopodioides* dominant bryophyte C21

16b. *Vaccinium membranaceum* not dominant dwarf shrub, *Hylocomium splendens* (occasionally *Pleurozium schreberi* or *Dicranum* spp.) dominant bryophyte 17

17a. Herb-dwarf shrub layer cover <15%, *Vaccinium scoparium* usually absent, Lower Subalpine C13

17b. Herb-dwarf shrub layer cover >15%, *Vaccinium scoparium* usually present, Lower or Upper Subalpine 18

18a. Herb-dwarf shrub layer dominated by *Phyllodoce glanduliflora* (or sometimes *Phyllodoce empetriformis*), herb cover low, Upper Subalpine C34

18b. Herb-dwarf shrub layer dominated by *Elymus innovatus*, *Arnica cordifolia* and *Linnaea borealis*, herb cover high, Lower Subalpine C31

18c. Herb-dwarf shrub layer dominated by *Vaccinium scoparium*, herb cover variable, Upper Subalpine C15

II. KEY TO OPEN FOREST TYPES

1a. Tree layer dominated by *Pinus flexilis*, often with *Pseudotsuga menziesii* O2

1b. Tree layer dominated by *Pseudotsuga menziesii* O5

1c. Tree layer dominated by mixture of *Picea* spp., *Abies lasiocarpa*, *Pinus albicaulis* and *Pinus contorta*; *Pseudotsuga menziesii* may be present at lower altitudes; usually on steep, colluvial, subxeric site (some open C35 may key here) O4

1d. Tree layer dominated by *Betula* spp. O16

1e. Tree layer dominated by *Picea glauca* and *Picea mariana* O7

1f. Tree layer dominated by *Pinus contorta* with prominent *Juniperus communis* and *Arctostaphylos uva-ursi* in understory ..... open variant of C3

1g. Tree layer dominated by *Picea glauca* or *Picea engelmannii*, *Abies lasiocarpa* may be codominant 2

2a. *Ledum groenlandicum* dominant shrub O11

2b. *Salix* spp. dominant shrub 3

2c. *Potentilla fruticosa* dominant shrub O3

2d. *Juniperus communis* dominant shrub O17

2e. Shrub layer sparse or dominated by tree regeneration 6

3a. *Salix vestita* dominant shrub 4

3b. Dominant shrub *Salix* spp. other than *Salix vestita* 5

4a. *Arctostaphylos rubra* dominant in herb-dwarf shrub layer O12

4b. *Pedicularis bracteosa* dominant in herb-dwarf shrub layer O14

5a. *Elymus innovatus* dominant herb, site mesic O18

5b. *Carex* spp. dominant herb, site hygric to hydric O6

6a. Herb-dwarf shrub layer dominated by *Dryas octopetala* O19

6b. Herb-dwarf shrub layer dominated by *Phyllodoce glanduliflora*, *Cassiope mertensiana* or other ericaceous dwarf shrubs O10

6c. Herb-dwarf shrub layer dominated by *Valeriana sitchensis*, *Erigeron peregrinus* or other herbs O9

III. KEY TO SHRUB VEGETATION TYPES

1a. *Abies lasiocarpa* (or occasionally *Picea engelmannii*) dominant shrub, snow avalanche path S2

1b. *Salix scouleriana* and *Alnus spp.* dominant shrubs, Jasper S6

1c. *Salix barrattiana* dominant shrub S8

1d. Various *Salix* spp., *Betula glandulosa* or *Betula pumila* dominant 2

2a. *Scirpus caespitosus* dominant herb S3

2b. *Kobresia myosuroides* dominant herb S9

2c. *Danthonia intermedia* dominant herb S11

2d. *Equisetum arvense* dominant herb S7

2e. None of the above 3

3a. *Potentilla fruticosa* usually present 4

3b. *Potentilla fruticosa* usually absent 5

4a. Bryoid cover dense, *Tomenthypnum nitens* present, *Arctostaphylos uva-ursi* usually absent, site subhygric to hydric, level to gentle slope S1

4b. Bryoid cover sparse, *Tomenthypnum nitens* absent, *Arctostaphylos uva-ursi* usually present, site mesic to subxeric, moderate to steep slope S10

5a. *Elymus innovatus* cover ≥10%, *Salix barrattiana* usually absent S12

5b. *Elymus innovatus* cover <10%, *Salix barrattiana* usually present (5-20%) S4

IV. KEY TO LOW SHRUB-HERB VEGETATION TYPES

Dominant low shrub *Potentilla fruticosa* L1

Dominant low shrubs *Juniperus communis* and *Salix glauca*, snow avalanche path L2

Dominant low shrub *Cassiope tetragona*, snowbed L4

Dominant low shrubs *Phyllodoce glanduliflora* and *Cassiope mertensiana* L5

Dominant low shrub *Juniperus horizontalis* L6

Dominant low shrub *Salix arctica* L7

V. KEY TO HERB-DWARF SHRUB VEGETATION TYPES

1a. *Dryas* spp. dominant or codominant 2

1b. *Dryas* spp. not dominant 4

2a. *Dryas drummondii* dominant H8

2b. *Dryas integrifolia* dominant, *Carex rupestris* codominant, Jasper only H15

2c. *Dryas octopetala* dominant, may contain *Dryas integrifolia* but *Carex rupestris* not codominant, see v.t. description for other differences 3

3a. *Kobresia myosuroides*, *Arctostaphylos uva-ursi* codominant H4

3b. *Salix nivalis*, *Silene acaulis* codominant H1

4a. Elevation <1700 m, subxeric to xeric grasslands 5

4b. Elevation mostly >1700 m, not subxeric to xeric grasslands 8

5a. *Agropyron* spp. dominant 6

5b. *Agropyron* spp. not dominant 7

6a. *Agropyron dasystachyum* dominant, *Artemisia frigida* codominant H7

6b. *Agropyron spicatum* usually dominant, *Elymus innovatus* often codominant H19

7a. *Koeleria cristata* dominant, *Artemisia frigida* codominant H6

7b. *Stipa richardsonii* dominant, *Koeleria cristata* codominant H13

8a. Site subhydric to hydric, very poorly drained 9

8b. Site drier and better drained 10

9a. *Eriophorum angustifolium* dominant H10

9b. *Carex aquatilis* or *Carex rostrata* dominant H11

9c. *Caltha leptosepala* and *Trollius albiflorus* codominant H9

10a. Lichens dominant, sparsely vegetated, high Alpine elevations H12

10b. Graminoids dominant 11

10c. Forbs dominant 14

11a. *Carex* spp. dominant 12

11b. *Elymus innovatus* dominant 13

12a. *Carex nigricans* dominant, Alpine snowbed H2

12b. *Carex scirpoidea* dominant, Montane-Lower Subalpine fluvial site H3

13a. *Fragaria virginiana*, *Epilobium angustifolium* abundant, site mesic H5

13b. *Koeleria cristata*, *Arctostaphylos uva-ursi* (*Hedysarum sulphurescens* in Banff) abundant, site subxeric H14

13c. *Saxifraga bronchialis* abundant, site xeric to subxeric H20

14a. Site subxeric to xeric, *Saxifraga bronchialis* and *Elymus innovatus* dominant H20

14b. Site mesic to hygric, *Saxifraga bronchialis* and *Elymus innovatus* usually absent 15

15a. *Caltha leptosepala* and *Trollius albiflorus* dominant H9

15b. *Erigeron peregrinus* and *Valeriana sitchensis* dominant H16

SUCCESSION AND CLIMAX

I.G.W. Corns and P.L. Achuff

INTRODUCTION

Although documentation of the pathways of vegetational succession was not one of the primary objectives of the Banff-Jasper Ecological Land Classification, the large amount of data collected allows the description of generalized successional trends and of seral and climax v.t.s. Succession deals with changes in vegetation over time. The time for vegetation to develop from early stages to climax ranges from more than a thousand years for the establishment of mature forest on recently deposited fluvial or morainal material (primary succession), to fewer than ten years for a mature grassland community to re-establish itself following fire (secondary succession).

The influence of fire on the vegetation of Banff and Jasper is very great, with nearly all of the present forest having been subject to fire in the past. Tande (1977) showed that the Athabasca River valley around Jasper townsite experienced major fires (>500 ha) in 24 of the years between 1665 and 1975, and that most of the present forest originated after fires in three years (1889, 1847, 1758). The potential complexity of successional relationships has been greatly simplified by the historical fire peak 100 to 120 years ago. This has resulted in the bulk of the *Pinus contorta* forests being approximately in the same successional stage. Earlier, preclimax stages are comparatively rare and are usually referable to a more common 100 to 120 years old v.t. Areas of recent burn are limited, e.g. Survey Peak - Saskatchewan Crossing and Flint's Park in Banff, lower Chaba River in Jasper.

Fire has several important roles in the environment which have been summarized by Wright and Heinselman(1973) and Tande (1977) as follows: 1) modifier of the physical-chemical environment, 2) regulator of dry matter accumulation, 3) controller of plant species composition and structure of plant communities, 4) determiner of wildlife habitat patterns and populations, 5) controller of forest insects, parasites and fungi, and 6) controller of major ecosystem processes and characteristics. Fire is unquestionably the major factor responsible for forest succession in Banff and Jasper. Fire is most influential upon the drier, lower elevation forests, shrub lands and grasslands where fuel accumulation is usually greater, trees are more closely spaced, and the climate is drier. In addition to fire, successional trends may be influenced by insects, diseases, climate, soil properties, and wildlife.

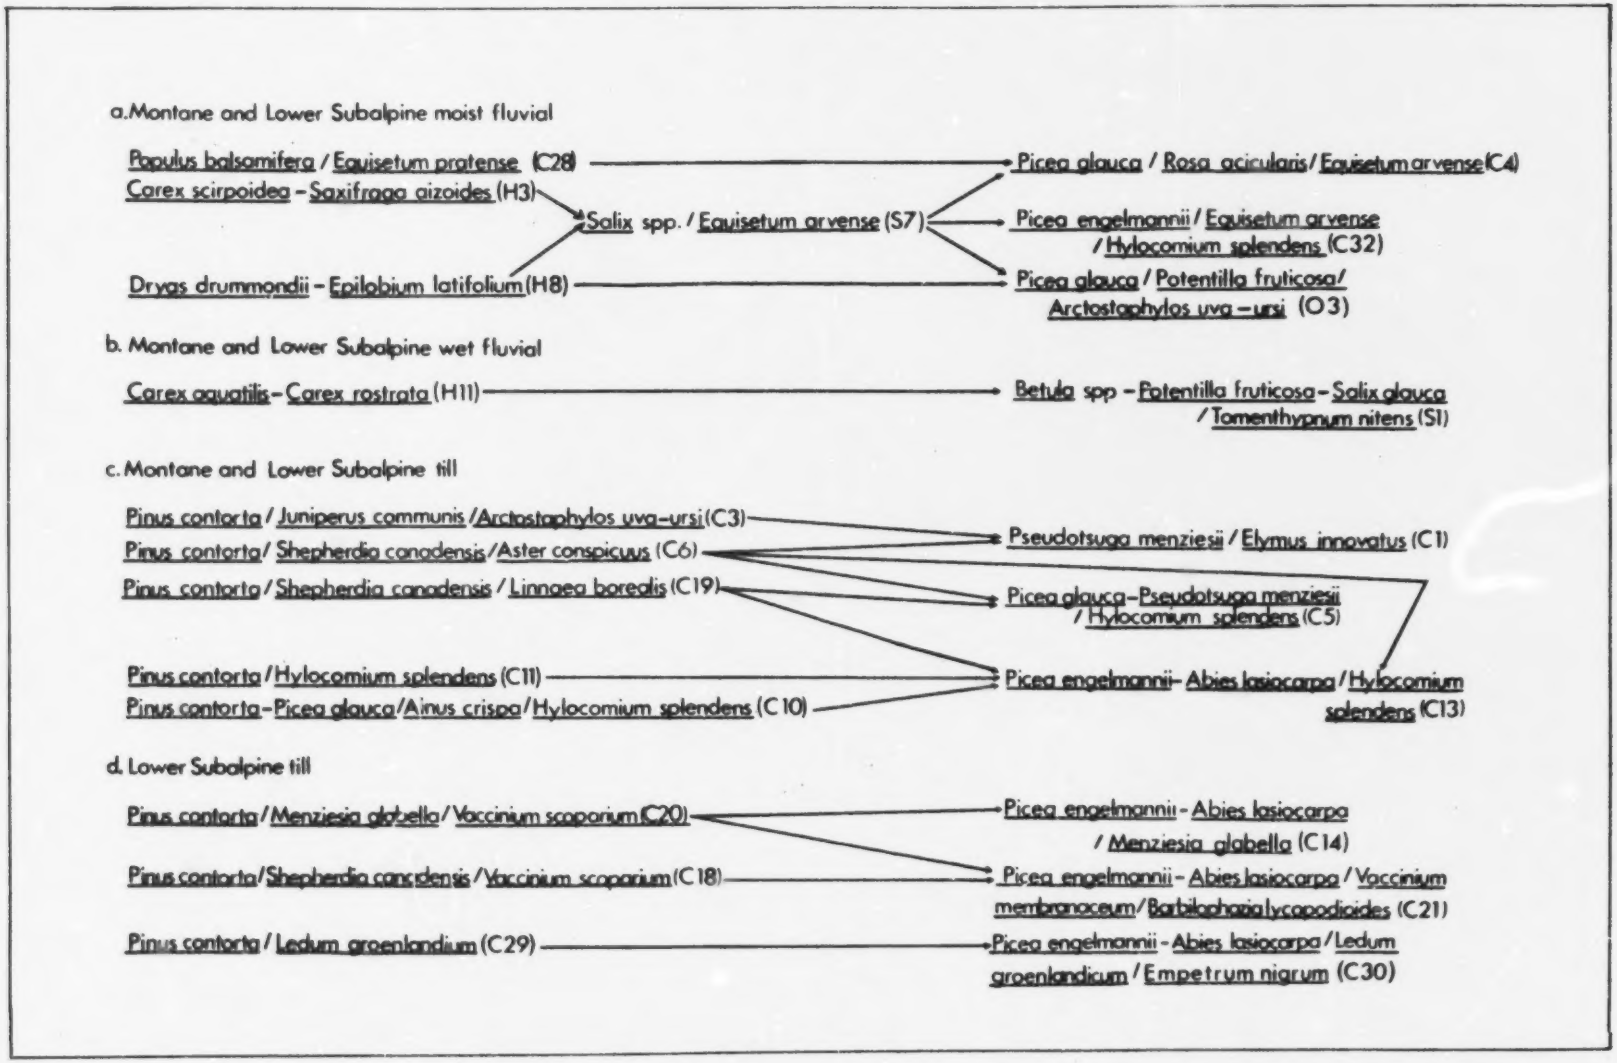
A four stage successional sequence is used in this report: early, intermediate, advanced and mature. Early successional stands are unstable, heterogeneous, often not referable to one of the v.t.s and usually less than 50 years has elapsed since stand origin after fire, flood or other major perturbation. Intermediate successional stands are moderately stable and dominated by species other than those climax for the site. Typically, they are dominated by *Pinus contorta* and show evidence of future dominance of climax species, e.g. *Picea engelmannii* and *Abies lasiocarpa* regeneration in a *Pinus contorta* forest. Successionally intermediate stands are usually 50 to 100 years old but may vary considerably from this range, since succession proceeds at different rates on different sites. Primary successions on recent floodplain or moraine, which may begin with, for example, yellow dryad-willow herb (H8) v.t. progressing through willow/horsetail (S7) v.t. and finally to stable white spruce/shrubby cinquefoil/bearberry (O3) v.t. (Fig. 23, part a), may take hundreds of years (Heusser 1956). Conversely, some stable *Picea* dominated v.t.s (e.g. white spruce/fern moss (C2) and white spruce/buffaloberry/feathermoss (C37) often show no evidence of a previous *Pinus contorta* stage and appear to pass through the intermediate stage relatively quickly. Advanced successional stands are generally 80 to 200 years old and are dominated by a mixture of seral and climax species. In forested v.t.s this is most typically a mixture of *Pinus contorta* and *Picea engelmannii* or *Abies lasiocarpa* (e.g. C11, C18, C29). The duration of this stage varies but 40 to 50 years is perhaps typical. Successionally mature (climax) v.t.s are stable, self perpetuating and the end points of plant succession. They are dominated by species best adapted to that environment and are in dynamic equilibrium with the prevailing climate and environment. Mature vegetation is the culmination of usually 150 years or more of plant succession but this time frame varies greatly as described above. The successional relationships of the v.t.s are discussed in the individual v.t. descriptions. General trends evident within the three Ecoregions are discussed below.

MONTANE ECOREGION

The Montane Ecoregion is predominantly forested and mature vegetation is characterized by *Pseudotsuga menziesii* and *Picea glauca* (e.g. Douglas fir/hairy wild rye (C1) on southerly aspects and white spruce-Douglas fir/feathermoss (C5) on northerly aspects), often successional from *Pinus contorta* dominated types such as lodgepole pine/juniper/bearberry (C3), lodgepole pine/buffaloberry/showy aster (C6), lodgepole pine/dwarf bilberry (C9) and lodgepole pine/buffaloberry/twinflower (C19) (Fig. 23, part c). Lodgepole pine/juniper/bearberry (C3) can achieve climax status on dry sites while on the driest Montane sites mature junegrass-pasture sage-wild blue flax (H6) and wheatgrass-pasture sage (H7) grassland v.t.s occur. Such grasslands may be maintained by frequent fires. On eolian landforms near the Jasper east gate and in the Saskatchewan Crossing area of Banff, *Picea* dominated white spruce/fern moss (C2), white spruce/buffaloberry/fern moss (C26), and white spruce/prickly rose/fern moss (C27) occur without any apparent distinct seral stages.

SUBALPINE ECOREGION

The Subalpine Ecoregion, also predominantly for-



a. Montane and Lower Subalpine moist fluvial
Populus balsamifera / Equisetum pratense (C28)
Carex scirpoidea - Saxifraga aizoides (H3)
Dryas drummondii - Epilobium latifolium (H8)
Salix spp. / Equisetum arvense (S7)
Picea glauca / Rosa acicularis / Equisetum arvense (C4)
Picea engelmannii / Equisetum arvense / Hylocomium splendens (C32)
Picea glauca / Potentilla fruticosa / Arctostaphylos uva-ursi (O3)
b. Montane and Lower Subalpine wet fluvial
Carex aquatilis - Carex rostrata (H11)
Betula spp - Potentilla fruticosa - Salix glauca / Tomenthypnum nitens (S1)
c. Montane and Lower Subalpine till
Pinus contorta / Juniperus communis / Arctostaphylos uva-ursi (C3)
Pinus contorta / Shepherdia canadensis / Aster conspicuus (C6)
Pinus contorta / Shepherdia canadensis / Linnaea borealis (C19)
Pinus contorta / Hylocomium splendens (C11)
Pinus contorta - Picea glauca / Alnus crispa / Hylocomium splendens (C10)
Pseudotsuga menziesii / Elymus innovatus (C1)
Picea glauca - Pseudotsuga menziesii / Hylocomium splendens (C5)
Picea engelmannii - Abies lasiocarpa / Hylocomium splendens (C13)
d. Lower Subalpine till
Pinus contorta / Menziesia glabella / Vaccinium scoparium (C20)
Pinus contorta / Shepherdia canadensis / Vaccinium scoparium (C18)
Pinus contorta / Ledum groenlandium (C29)
Picea engelmannii - Abies lasiocarpa / Menziesia glabella (C14)
Picea engelmannii - Abies lasiocarpa / Vaccinium membranaceum / Barbilophozia lycopodioides (C21)
Picea engelmannii - Abies lasiocarpa / Ledum groenlandicum / Empetrum nigrum (C30)

Figure 23 Some plant succession trends evident in Banff and Jasper National Parks.

ested, has mature vegetation dominated by *Picea engelmannii* and *Abies lasiocarpa* (e.g. Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/false azalea (C14), and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) in the lower portion of the Subalpine), often successional from *Pinus contorta* forests (e.g. lodgepole pine/buffaloberry/ twinflower (C19), lodgepole pine/false azalea/grouseberry (C20), and lodgepole pine/Labrador tea (C29) respectively; Fig. 23, part d). Successional trends are often less evident in the Upper Subalpine where the role of *Pinus contorta* as a seral species is minor. Common Upper Subalpine v.t.s (e.g. Engelmann spruce-subalpine fir/heather (O10), Engelmann spruce-subalpine fir/grouseberry (C15), and Engelmann spruce-subalpine fir/rock willow/ white mountain heather (C24) originate as *Picea-Abies* forests after fire. Succession proceeds more slowly at higher elevations often requiring 250 years or more to reach climax.

ALPINE ECOREGION AND WETLANDS

Successional processes in the Alpine Ecoregion and in Subalpine and Montane wetlands are somewhat different than in the forest. Due to the usual absence of fire, the major agents of disturbance are water erosion and, in the Alpine, cryogenic processes. Plant succession in the Alpine can be extremely slow. The present, often sparse, vegetation characteristic of this harsh environment, e.g. mountain avens-snow willow-moss campion (H1), represents development during the several thousand years since glacial retreat. Complete recovery of vegetation after trampling may take hundreds of years in some areas (Willard and Marr 1971). Distinct seral stages are less evident in Alpine areas than in Subalpine or Montane forests, and have not been recognized due to the greater difficulty of determining stand history in the Alpine v.t.s versus Subalpine forest where techniques such as increment coring may be used.

Wetland v.t.s in the Alpine, Subalpine, and Montane Ecoregions are also often characterized by slow successional processes and their characteristic herbaceous or shrubby vegetation can make stand history determination difficult. Vegetation development, often coincident with, for example, peat buildup, can be extremely slow and in the order of hundreds of years (Fig. 23, part b). For this reason most herb (H), low shrub-herb (L) and shrub (S) dominated types are usually designated as successionally mature, i.e. they are relatively stable within a 50 to 100 year time span. Geomorphological processes such as stream aggradation, erosion, cryoturbation, and peatland development cause landscape changes that are often coincident with normal vegetation successional processes, thus confounding successional history determination.

SIGNIFICANT SPECIES

P.L. Achuff and I.G.W. Corns

VASCULAR PLANTS

INTRODUCTION

During the Ecological Land Classification, four species of vascular plants new to Alberta were collected: *Hippuris montana* Ledeb., *Sedum divergens* Watson, *Tsuga heterophylla* (Raf.) Sarg., *Vaccinium ovalifolium* J.E. Smith. In addition, 148 species have been classified as rare and thus, are deserving of special management consideration. Other species have been identified as of interest because they are nearly rare or have a geographic range boundary within Banff and Jasper. This section provides information on species in all three categories.

Specimens are deposited in one or more of the following herbaria: CAFB (Northern Forest Research Centre, Edmonton), ALTA (University of Alberta), CAN (National Museum, Ottawa), DAO (Central Experimental Farm, Ottawa), NY (New York Botanical Garden, Bronx). Collector's names are abbreviated as follows: DK (D. Karasiuk), IC (I. Corns), JC (J. Cuddeford), JD (J. Dyck) , JE and JEM (J. Marsh), LC (L. Cole), PA and PLA (P. Achuff), SJ (S. Scott). Figure 24 shows the location of features cited below which are not on National Topographic Survey maps.

NEW TO ALBERTA

Hippuris montana Ledeb.: *Range* - Alaska, Yukon, Northwest Territories, British Columbia, western Alberta, Washington. *Alberta* - (Fig. 25) Jasper National Park: Catacombs Mt. (IC misc. 28 Sep 76), Divergence Creek (IC misc. 20 Sep. 77), Upper Lick Creek (IC misc. 19 Aug 77), Miette Pass (IC misc. 29 Jul 79). *Habitat* - shallow stream margins, wet mossy depressions, Alpine.

Sedum divergens Watson: *Range* - Cascade and Olympic Mountains of Washington, British Columbia, extreme southeastern Alaska, Klamath Mountains of Oregon. *Alberta* - (Fig. 26) Jasper National Park: Derr Creek (IC9141), Upright Pass (IC misc. 25 Jul 79), Corral Creek (JE misc. 10 Sep 79), Miette Pass (IC misc. 29 Jul 79), Mt. Thornton (PLA3651), Mt. Ranee (PLA3682), Mt. Bridgland (IC misc. 9 Sep 77). *Habitat* -

Figure 27 Distribution of *Tsuga heterophylla* in Banff and Jasper.

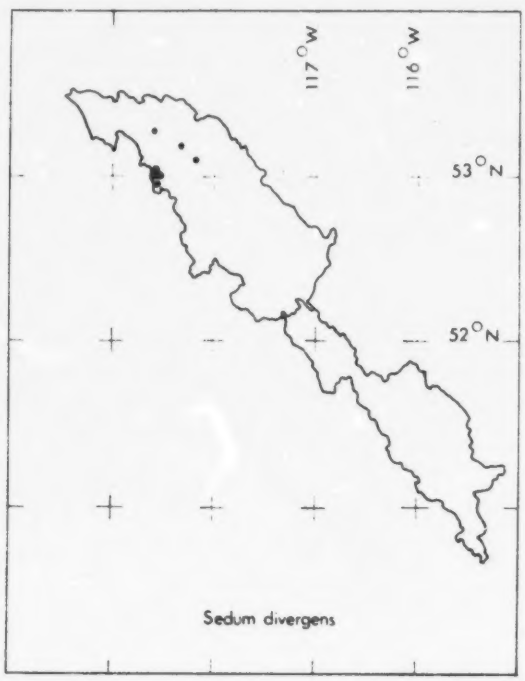

Figure 26 Distribution of *Sedum divergens* in Banff and Jasper.

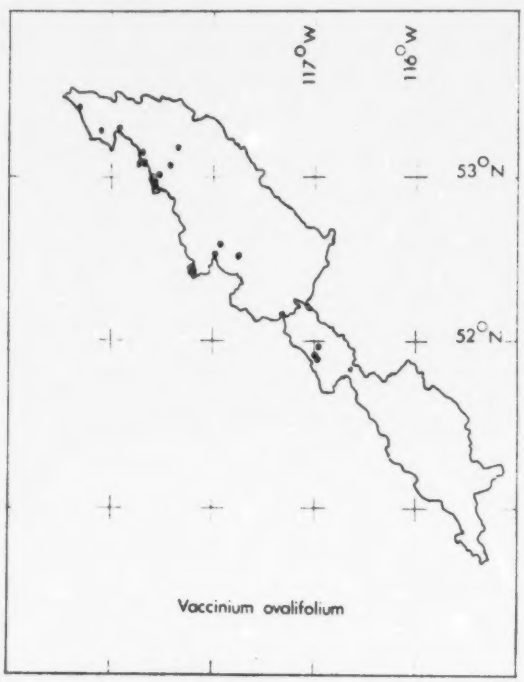

Figure 28 Distribution of *Vaccinium ovalifolium* in Banff and Jasper.

rocky slopes and ledges, avalanche slopes, Lower and Upper Subalpine.

Tsuga heterophylla (Raf.) Sarg.: *Range* - southern Alaska to California, interior British

Columbia from 55° to northwestern Montana, western Alberta. *Alberta* - (Fig. 27) Banff National Park: Coleman Creek (PLA misc. 7 Jun 77), Alexandra River (JD misc. 8 Aug 77), Castleguard River (DK misc. Jun 76), Jasper National Park: Fryatt Creek (IC misc. 17 Aug 77), Whirlpool River (SJ misc. 20 Sep 78). *Habitat* - moist *Picea engelmannii-Abies lasiocarpa* forests, Lower Subalpine.

Vaccinium ovalifolium J.E. Smith: *Range* - Alaska, British Columbia, western Alberta, Washington, Oregon, Idaho, western Montana, isolated areas in Ontario, Michigan, Quebec, Nova Scotia, Labrador and Newfoundland, also eastern Asia. *Alberta* - (Fig. 28) Banff National Park: Arctomys Creek (PA7069), Glacier Lake (PA7094), Southeast Lyell Glacier (PLA misc. 4 Aug 77), Chephren Lake (IC 7045). Jasper National Park: Canoe Pass (JC misc. 9 Aug 77), Snake Indian River - Hoodoo Cabin (JE9103.1), Geraldine Lakes (PLA3724), Mt. Beaupre (IC misc. 29 Jul 79), Mt. Knight (IC9080), Short Creek (IC9098), Upright Pass (IC9122), Mt. Thornton (PLA3694), Swoda Mtn. (LC misc. 23 Jul 79), upper Miette River (IC7080), Miette River (IC misc. 13 Aug 79), Lick Creek (IC misc. 19 Aug 77), Divergence Creek (IC 20 Sep 77). *Habitat* - moist *Picea engelmannii-Abies lasiocarpa* forests, Lower Subalpine.

All four of these species have small populations of limited range in the parks and are rare as defined below.

RARE SPECIES

In compiling a list of rare species, two recent works on rare plants in Alberta by Argus and White (1978) and Packer and Bradley (1978) have been consulted. Argus and White (1978) define a rare plant as "one that has a small population in the province...restricted to a small geographical area (usually less than 3900 sq.km.) or it may occur sparsely over a wide area." Packer and Bradley (1978) consider a rare species to be known from $\leq$10 localities. In Banff and Jasper, a rare plant is considered to occur within a restricted geographic area, usually $<$500 sq.km., and at usually $<$10 collection sites; also, the plant is often at the edge of its geographic range. All three criteria usually indicate a small population in the parks. With a few exceptions, plants considered rare in the province are also considered rare in Banff and Jasper.

In the list below, B indicates occurrence in Banff and J occurrence in Jasper. The comments with each species indicate its range and habitat in the parks as presently known. Information for species on the list which were not seen during the inventory is derived largely from Argus and White (1978) and Packer and Bradley (1978).

Agroelymus xmossii Lepage: B, Lake Louise area, pine forests, Lower Subalpine, a hybrid of *Agropyron trachycaulum* and *Elymus canadensis*.

Agropyron violaceum (Hornem.) Lange spp. *andinum* (Scribn. & Sm.) Meld.: B, Sunwapta Pass, moist meadows, Upper Subalpine.

Agrostis borealis Hartm.: B, Paradise Valley, J, Mt. Edith Cavell, moist meadows, Upper Subalpine.

Agrostis humilis Vasey: B, Healy Ck., Lost Horse Ck., Sunshine, J, Marble Mtn., meadow, Upper Subalpine.

Agrostis thurberiana Hitch.: B, Simpson Pass, J, Centre Pass, Mt. Pattison, moist meadow, Lower and Upper Subalpine.

Antennaria acuta Rydb.: B.

Antennaria alpina (L.) Gaertn. var. *media* (Greene) Jeps.: B, Glacier L., Molar Pass, Goat Ck., J, Chaba River, Whirlpool River, meadow and tundra, Upper Subalpine and Alpine.

Antennaria angustata Greene: B, Cyclone cabin, J, Mt. Edith Cavell, Derr Ck., Smoky cabin, meadow, Upper Subalpine and Alpine.

Antennaria corymbosa E. Nels.: B, Sunshine, Clearwater R., J, Brazeau R., Lower and Upper Subalpine.

Antennaria luzuloides T. & G.: J.

Antennaria monocephala DC: B, Dolomite Ck., J, Rocky R., Mt. Ranee, tundra, Alpine.

Aquilegia jonesii Parry: J, east gate, Montane.

Arenaria humifusa Wahl.: B,J.

Arenaria nuttallii Pax: J, Corral Ck., Pyramid Mtn., dry ridges, Alpine.

Arnica alpina (L.) Olin ssp. *angustifolia* (M. Vahl) Maguire: B,J, meadows, Upper Subalpine and Alpine.

Arnica longifolia D.C. Eaton: B,J.

Arnica parryi Gray: B, Helen Ck. trail, J, Portal Ck., spruce-fir forest, Lower Subalpine.

Artemisia borealis Pall.: J, dry slopes, Upper Subalpine and Alpine.

Aster maccallae Rydb.: B,J, streamsides, Lower Subalpine

Athyrium alpestre (Hoppe) Rylands: J, rocky slopes, Upper Subalpine and Alpine.

Botrychium boreale (Fries) Milde: B, Siffleur R., Sentinel Pass, moist meadows, Upper Subalpine.

Botrychium lanceolatum (Gmel.) Angstr.: B, Mt. Temple, J, Colonel Pass, moist meadows, Upper Subalpine.

Braya purpurascens (R.Br.) Bunge: J, rocky slopes, Alpine.

Bromus purgans L.: B, moist forest, Lower Subalpine.

Carex athabascensis Hermann: J, Calumet Ck., moist meadow, Lower Subalpine.

Carex bigelowii Torr.: B, dry slopes, Alpine.

Carex bipartita Allioni: B, Ptarmigan L., Divide Ck., meadow, Upper Subalpine and Alpine.

Carex crawei Dewey: B,J, wet meadow, Upper Subalpine and Alpine.

Carex eleusinoides Turcz.: J, Mt. Edith Cavell, wet meadow, Upper Subalpine and Alpine.

Carex glacialis Mack.: B, Mt. Brewster, dry meadow, Upper Subalpine and Alpine.

Carex illota Bailey: B, Simpson Pass, J, Geraldine L. trail, wet meadow, Upper Subalpine and Alpine.

Carex interior Bailey: B, Rockbound L. trail, Saskatchewan Crossing, J, Warden Office, streamsides, Montane to Upper Subalpine.

Carex lenticularis Michx.: J, Smoky cabin, sedge fen, Lower Subalpine.

Carex limnophila Hermann: B, J, moist meadow, Lower and Upper Subalpine.

Carex loliacea L.: J, Portal Ck., Jasper townsite, moist woods, Montane to Upper Subalpine.

Carex mertensii Prescott: J, Geraldine Lookout road, moist forest, Lower and Upper Subalpine.

Carex misandra R.Br.: J, tundra, Alpine.

Carex petricosa Dewey: B, Sunwapta Pass, J, Beaver Lake, Colonel Pass, Mt. Edith Cavell, Medicine Tent R., rocky outcrops and meadows, Upper Subalpine and Alpine.

Carex supina Willd. ssp. *spaniocarpa* (Steud.) Hult.: B, Sunshine, meadow, Upper Subalpine.

Carex vesicaria L.: B, wet meadow, Upper Subalpine and Alpine.

Castilleja hispida Benth.. B, Mt. Norquay, pine forest, Lower Subalpine.

Clintonia uniflora (Schult.) Kunth: J, Smoky cabin, moist forest, Lower Subalpine.

Corispermum hyssopifolium L.: J, Talbot L., sand dune, Montane.

Crepis atrabarba Heller: B, dry grasslands, Montane and Lower Subalpine.

Crepis intermedia A. Gray: B, Cory Pass trail, dry grassland, Montane.

Cryptantha affinis (Gray) Greene: B, grassy slopes, Lower Subalpine.

Cypripedium montanum Dougl.: J, Banff-Jasper Hwy., moist forest, Lower Subalpine.

Cystopteris montana (Lam.) Bernh. J, Canoe Pass, moist forest, Lower Subalpine.

Draba albertina Greene: B, Sawback L., Rockbound L., J, Pyramid Mtn., meadow, Upper Subalpine and Alpine.

Draba densifolia Nutt.: B, talus slopes, Upper Subalpine.

Draba fladnizensis Wulf.: B, Divide Ck., J, tundra, Alpine.

Draba glabella Pursh: J, Columbia Icefields, Signal Mtn., Upper Subalpine and Alpine.

Draba kananaskis Mulligan: J, Maligne Lk., open forest, Lower and Upper Subalpine.

Draba longipes Raup: J, Sassanach Mtn., Medicine Tent R., Portal Ck., meadow, Upper Subalpine and Alpine.

Draba reptans Lam.: B, Cory Pass trail, dry grassland, Lower Subalpine.

Draba ventosa Gray: J, Opal Hills, rocky outcrop, Alpine.

Drosera anglica Huds.: Fryatt Ck., wet shrub meadow, Lower Subalpine.

Drosera linearis Goldie: B, sedge fen, Lower Subalpine.

Dryopteris assimilis S. Wats.,: B, Forbes Ck., Mt. Eisenhower, J, Quincy Ck., Pyramid L., Portal Ck., Moab L., Lynx Ck., Miette L., Lick Ck., moist forest, Lower and Upper Subalpine.

Dryopteris fragrans (L.) Schott.: J, Maligne L., Geraldine L. trail, Lower Subalpine.

Epilobium luteum Pursh: B, J, Lynx Ck., Lower Subalpine.

Erigeron flagellaris Gray: J, Mina L., Montane.

Erigeron ochroleucus Nutt.: B, Saskatchewan Crossing, Indianhead Ck., J, Talbot L., dry meadow, Montane to Lower Subalpine.

Erigeron pallens Cronq.: B, Eagle Mtn., Quartz Ridge, J, Wall Pass, talus, Upper Subalpine and Alpine.

Erigeron scotteri Boiv.: B, J, Alpine.

Eriophorum callitrix Cham.: B, Snow Creek Pass, J, Whistler's Mtn., cottongrass fen, Alpine.

Erysimum pallasii (Pursh) Fern.: B, Sunset Pass, Whitehorn Mtn., J, Resthaven Icefield, Wilcox Pass, Mt. Simla, Mt. Oliver, Bald Hills, talus and tundra, Alpine.

Festuca subulata Trin.: B, Molar Mtn., grassland, Upper Subalpine.

Festuca viridula Vasey: J, grassland.

Galium palustre L.: J, moist meadow.

Gaultheria humifusa (Grah.) Rydb.: B, Glacier L., Bow Pass, J, Blue Creek, Mt. Davidson, Mt. Catacombs, Windy Castle, Knight Ck., Divergence Ck., Miette Pass, Trapper Ck., Resthaven Icefield, Amethyst L., moist forest, Upper Subalpine.

Gentiana glauca Pallas: B, Dolomite Pass, Redoubt L., J, Maligne R., Marble Mtn., Marmot Mtn., Pyramid Mtn., Signal Mtn., meadow, Upper Subalpine and Alpine.

Geranium erianthum DC.: J, dry grassland, Montane.

Habernaria unalascensis (Spreng.) S. Wats.: B, J.

Haplopappus uniflorus (Hook.) T. & G.: B, Saskatchewan Crossing, J, Willow Ck., wet meadow, Montane and Lower Subalpine.

Heuchera glabra Willd.: J, Whirlpool R., Moab L., Mt. Edith Cavell, Lower Subalpine.

Hieracium albertinum Farr.: B, Healy Ck., Paradise Valley, Upper Subalpine.

Hierochloe alpina (Sw.) R. and S.: J, Marmot Basin, Signal Mtn., Mt. Edith Cavell, Pyramid Mtn., Mt. Kerr,

Azure L., Swoda Ck., meadows and tundra, Upper Subalpine and Alpine.

Isoetes muricata Dur.: J, lake shore, Lower Subalpine.

Juncus biglumis L.: B, J, Mt. Edith Cavell, wet meadow and tundra, Upper Subalpine and Alpine.

Juncus parryi Engelm.: B, Flint's Park turn-off, Lower Subalpine.

Juncus stygius L. var. *americanus* (Buch)Hult.: B, Lake Louise, fen, Lower Subalpine.

Koenigia islandica L.: J, Mt. Edith Cavell, Whistler's Mtn., wet meadow, Upper Subalpine.

Lesquerella arctica (Wormsk.)S. Wats.: B.

Listera caurina Piper: B, Lake Louise, J, Roche De Smet, pine forest, Lower Subalpine.

Lithophragma glabrum Nutt.: B.

Lithophragma parviflora (Hook.) Nutt.: B, dry grassland, Montane.

Loiseleuria procumbens (L.)Desv.: J, Outpost L., Topaz L., Linda L., Azure L., Blue Ck., Mt. Edith Cavell, Resthaven Icefield, rocky outcrops, Upper Subalpine.

Lupinus nootkatensis Donn: J, Byng cabin, Twintree L., Miette R., Mt. Simla, Tonquin Valley, Snaring R., Canoe Pass, Resthaven Icefield, moist meadow, Upper Subalpine.

Luzula arcuata (Wahl.) Sw.: B, Ptarmigan L., J, Linda L., Calumet Ridge, Bald Hills, Pyramid Mtn., Mt. Edith Cavell, tundra, Alpine.

Lycopodium sitchense Rupr.: B, Fish L., J, Upright Pass, Blue Ck., Lick Ck., Snake Indian Mtn., Catacombs Mtn., Divergence Ck., Smoky cabin, moist meadow, Upper Subalpine and Alpine.

Melica spectabilis Scribn.: B, Sunshine, meadow, Upper Subalpine.

Mimulus lewisii Pursh: J, Snaring R., Lower Subalpine.

Mitella breweri A. Gray: B, Marvel Pass, Sunshine, moist forest, Upper Subalpine.

Osmorhiza chilensis Hook. & Arn.: B, Mt. Murchison, Mt. Eisenhower, J, Mt. Christie, moist forest, Lower and Upper Subalpine.

Osmorhiza purpurea (Coult. & Rose) Suksd.: J, Ranee Mtn., moist forest, Lower Subalpine.

Panicum occidentale Scribn.: B, wet meadow, Montane.

Papaver freedmanianum D. Love: J, Opal Hills, Alpine.

Papaver kluanensis D. Love: B, Siffleur R., Gibbon Pass, Divide Ck., J, Mt. Simla, Mt. Tekarra, Smoky cabin, tundra and talus, Alpine.

Pedicularis arctica R.Br.: B, Indianhead Ck., Carrot Ck. Pass, Peters Ck., J, Pyramid Mtn., Mt. Edith Cavell, Signal Mtn., Jonas Ck., Snowbowl, Marble Mtn., tundra, Alpine.

Pedicularis contorta Benth.: B, Whitehorn Mtn., Stony Ck., Healy Ck., Molar Mtn., Spray R., Sentinel Pass, tundra, Alpine.

Pedicularis flammea L.: B, Douglas L., Panther Mtn., Dormer Pass, Divide Ck., Fortymile Ck., J, Cairn Pass, Rocky Forks, Whitehorse cabin, Restless R., Wilcox Pass, tundra, Alpine.

Pedicularis lanata Cham. & Schlect.: J, Vine Creek, Little Heaven cabin, Mt. Stornaway, Blue Ck., Rocky R., Whitehorse cabin, open forest and tundra, Upper Subalpine and Alpine.

Pedicularis racemosa Dougl.: B, Marvel L., J, Maligne L., Palisades Lookout, meadow, Upper Subalpine.

Pellaea atropurpurea (L.)Link: B, Tunnel Mtn., calcareous cliffs, Montane.

Pellaea glabella Mett. var. *occidentalis* (E. Nels.) Butters: B, Tunnel Mtn., Mt. Rundle, Sawback Range, J, Jasper townsite, cliffs, Montane.

Penstemon fruticosus (Pursh) Greene var. *scouleri* (Lindl.)Cronq.: B, Douglas L., Spray R., Marvel L., J, Waterfalls cabin, Verdant Pass, Portal Creek, rocky slopes, Lower and Upper Subalpine.

Phyllodoce intermedia (Hook.)Camp: B, Molar Pass, Dolomite Pass, J, Brazeau R., meadow, Upper Subalpine and Alpine.

Plantago canescens Adams: J, Pyramid L., Montane.

Poa lanata Scribn. & Mer.: B.

Poa lettermanii Vasey: B,J, Whistler's Mtn., meadow, Upper Subalpine and Alpine.

Poa stenantha Trin.: B, Lake Agnes, Whitehorn Mtn., open forest, Upper Subalpine.

Primula egaliksensis Wormsk.: J, Pyramid L., Kidney L., moist meadow, Montane and Lower Subalpine.

Primula stricta Hornem.: J, Roche De Smet, Willow Ck., wet meadow, Lower Subalpine.

Pteridium aquilinum (L.)Kuhn: B,J, Short Ck., moist forest, Lower Subalpine.

Ranunculus gelidus Karel. & Kiril.: B, Hillsdale, Lower Subalpine.

Ranunculus nivalis L.: J, Signal Mtn., Mt. Stornoway, meadow, Alpine.

Ranunculus occidentalis Nutt. var. *brevistylis* Greene: J, Swoda Ck., Caribou Lks., Chetang Ridge, Moose Pass, Adolphus L., Linda L., Mowich Ck., Mt. Beaupre, Miette Pass, Upright Pass, Whistler's Mtn., moist meadow, Alpine.

Ranunculus verecundus Robins.: B, Bryant Ck., Ptarmigan L., J, Rocky R., meadow, Upper Subalpine.

Rhododendron lapponicum (L.)Wahlenb.: J, Southesk R., open forest, Lower and Upper Subalpine.

Ribes laxiflorum Pursh.: B, Chephren L., J, Roche De Smet, upper Athabasca R., Geraldine Lks. trail, moist forest,

Lower Subalpine.

Rorippa obtusa (Nutt.)Britt.: B, Owl L., lakeshore, Lower Subalpine.

Rubus chamaemorus L.: J, Smoky cabin, wet forest, Lower Subalpine.

Salix alaxensis (Anderss.)Cov.: J, Wall Pass, Tie Camp, shrubby meadow, Lower and Upper Subalpine.

Salix lanata L. ssp. *calcicola* (Fern. & Weig.)Hulten: B, Malloch Ck., Saskatchewan Crossing, J, Whirlpool R., meadow, Lower Subalpine.

Salix novae-angliae Anderss.: B, Saskatchewan Crossing, floodplain, Lower Subalpine.

Salix reticulata L. ssp. *reticulata*: J, Southesk L., Restless R., Waterfalls Cabin, streamside, Lower Subalpine.

Salix sitchensis Sans.: J, Athabasca R., riverbank, Lower Subalpine.

Salix stolonifera Cov.: J, Opal Hills, meadow, Alpine.

Saxifraga arguta D. Don: J, Lynx CK., Colonel Pass, Portal Ck., Meadow, Upper Subalpine.

Saxifraga debilis Engelm.: B, Clearwater Pass, Lost Horse Ck., J, Calumet Ridge, Topaz L., seepy cliffs, Upper Subalpine and Alpine.

Saxifraga flagellaris Willd.: B, Indianhead Ck., J, Roche De Smet, tundra, Alpine.

Saxifraga nivalis L.: B, Sentinel Pass, Sunset Pass, J, Wilcox Pass, Signal Mtn., meadow, Upper Subalpine and Alpine.

Saxifraga punctata L.: B,J, Mt. Edith Cavell, Mt. Simla, Mt. Thornton, meadow, Upper Subalpine.

Scirpus hudsonianus (Michx.)Fern.: J, Smoky cabin, sedge fen, Lower Subalpine.

Silene furcata Raf. (=*Lychnis affinis* J. Vahl):B.

Smilacina trifolia (L.)Desf.: J, Miette Hot Springs Rd., Celestine Rd., wet forest, Montane and Lower Subalpine.

Sorbus sitchensis Roemer: B, Lake Louise, J, Blue Ck., Lynx Ck., moist forest, Lower and Upper Subalpine.

Sparganium hyperboreum Laest.: B, Simpson Pass, J, Tonquin Valley, Lower Subalpine.

Stellaria americana Porter: J, Jonas Pass., Alpine.

Stellaria umbellata Turcz: B, Taylor L., meadow, Upper Subalpine.

Telesonix jamesii Rydb.: J, Restless R., Cinquefoil Mtn., Lower Subalpine.

Thelypteris phegopteris (L.) Slossen: J, moist forest. Lower Subalpine .

Thuja plicata D. Don: B, Glacier L., Survey Pk., Castleguard R., Lower Subalpine.

Tofieldia coccinea Tich J, Athabasca R., Montane.

Veronica salina Schur: B, Cascade Power House, stream edge, Montane.

Viola selkirkii Pursh: J, Mt. Edith Cavell, moist forest,Lower Subalpine.

Woodsia glabella R.Br.: B,J, moist cliffs, Lower Subalpine.

OTHER SPECIES

These species include those which are special because they are nearly rare or they have a geographic range boundary in the parks. The comments with each species indicate the special interest.

Arnica louiseana Farr: nearly rare.

Artemisia norvegica Fries: southern range boundary in northern Banff.

Berberis repens Lindl.: northern range boundary in southern Banff.

Campanula uniflora L.: nearly rare.

Castilleja raupii Pennell: southern range boundary in central Jasper.

Castilleja rhexifolia Rydb.: northern range boundary in central Jasper.

Chimaphila umbellata (L.) Bart.: nearly rare.

Claytonia megarrhiza (A. Gray) Parry: northeastern range boundary in northern and eastern Banff.

Draba macounii O.E. Schulz: nearly rare.

Dryas integrifolia Vahl: nearly rare.

Erythronium grandiflorum Pursh.: range extension to northern Jasper.

Festuca idahoensis Elmer: nearly rare. northern range boundary in southern Banff.

Hedysarum sulphurescens Rydb.: northern range boundary in northern Banff.

Juniperus scopulorum Sarg: northern range boundary in southern Banff.

Larix laricina (DuRoi) K. Koch: western range boundary in central Jasper.

Larix lyallii Parl.: northern range boundary in central Banff.

Ledum glandulosum Nutt.: range boundary in southern Banff.

Mitella trifida Graham: nearly rare.

Muhlenbergia richardsonis (Trin.) Rydb.: nearly rare.

Picea mariana (Mill.) BSP: southern range boundary in northern Banff.

Pinus flexilis James: northern range boundary in northern Banff.

Potentilla glandulosa Lindl.: nearly rare.

Sedum roseum (L.) Scop.: northern range boundary in central Banff.

Stipa comata Trin. and Rupr.: nearly rare.

Thermopsis rhombifolia (Nutt.) Richards: nearly rare.

Vaccinium myrtilloides Michx.: nearly rare.

Vaccinium scoparium Leiberg: northern range boundary in northern Jasper.

Vaccinium uliginosum L.: nearly rare.

NONVASCULAR PLANTS

INTRODUCTION

The selection of rare liverworts and mosses is based primarily on information provided by

Dr. D.H. Vitt, Department of Botany, University of Alberta. The lichen information was supplied by J. Marsh, Alberta Institute of Pedology. The status "rare" is based on an abundance scale (dominant, common, infrequent, uncommon, rare) reflecting the quantity of the taxon in Banff and Jasper; its abundance may be quite different in other parts of its range. This approach differs from that used for the vascular plants because the ranges and abundances of nonvascular plants are much less well known. B or J means collected only in Banff or Jasper; taxa with neither occur in both parks.

LIVERWORTS: RARE SPECIES

Anthelia julacea (L.)Dum., J.
Asterella ludwigii (Schwaegr.) Underw., J.
Athalamia hyalina (Sommert.) Hatt., B.
Calypogeja integristipula Steph., J.
Calypogeja neesiana (Mass. & Carest.) K. Muell., J.
Calypogeja suecica (H. Arnell & J. Perss.) K. Muell., J.
Geocalyx graveolens (Schrad.) Nees, J.
Gymnomitrion concinnatum (Lightf.) Corda, J.
Harpanthus flotovianus (Nees) Nees, J.
Lophozia rutheana (Limpr.) M.A. Howe, J.
Marsupella sphacelata (Gieseke) Dum., J.
Radula complanata (L.) Dum., J.
Scapania undulata (L.) Dum., J.

MOSSES: RARE SPECIES

Amblystegium varium (Hedw.) Lindb.
Aulacomnium turgidum (Wahlenb.) Schwaegr., J.

PHILOSOPHICAL PRINCIPLES GOVERNING THE DEVELOPMENT OF THE ECOLOGICAL METHODOLOGY

G. M. Coen, B. D. Walker, and W. S. Taylor

INTRODUCTION

In the late 1960's during public hearings on Park's master plans, Park authorities supported conservation groups recommendations that adequate base level data on natural resources were prerequisite for responsible planning and management of Canada's National Parks (East et al. 1979). A pilot project in Waterton Lakes National Park collected and presented resource information (soils, geology, forest cover, habitat type, wildlife species distribution, archeological sites) as independent reports on each resource sector. The resource data were gathered at differing mapping intensities and scales with the result that data integration by the planning teams became complex and difficult. To simplify the use of resource inventory data for planning, consideration was given to an integrated (biophysical) approach to resource inventory (Lacate 1969). Thus, when separate contracts were let for the vegetation and physical resource sectors in Yoho National Park, the research teams were also requested to compile a biophysical map after the field work was completed. When the two teams began to combine the soils and vegetation data into a biophysical map it was apparent that slight modification of original mapping concepts would have produced a map with more consistent repeating ecological map concepts. The fact that both teams used essentially closed legends facilitated the merger of the two data bases and assisted in the development of biophysical map concepts which would have otherwise been much less apparent (closed and open legends are discussed in the next section).

These experiences reinforced the developing ideas that not only should all resource sectors be linked to one set of polygons but also that the map legend should define holistic, repeating ecological map unit concepts. A pilot project was undertaken in the Lake Louise area in 1974 (Holland 1976, Walker et al. 1978) to develop and test a land classification methodology appropriate to the needs of the Mountain National Parks. The following discussion is background for the methodology used to map Banff and Jasper National Parks.

UNDERLYING PRINCIPLES

Three important guidelines were used in developing the ecological mapping procedures for Banff and Jasper.

1. The map, legend and report shou'd be easily interpretable to assist in management decisions;
2. The map unit concept (Ecosite in this case) should be repetative and holistic so that information obtained about land use response in a familiar area can be transferred to a similar but unfamiliar area;
3. Mapped information should be of uniform intensity and reliability throughout.

With reference to the first guideline, the map, legend and report should be easily interpretable to assist in management decisions. The design of the legend and map symbols can greatly facilitate interpretations (Coen 1973).

Maps made with multifactor, open legends resulting in symbols like $\frac{3\,MOB\text{-}SHP2}{3A:4A}$ 2mfT and (Fig.8 in Gimbarzevsky 1976) are difficult to interpret (read and remember) for specific land uses. The symbol denotes a hill, 2 indicates a well drained site, mf indicates moderately fine texture and T indicates a till deposit. The first 3 indicates accompanying vegetation 21 to 40 feet high, maple-oak-birch species group and spruce to hemlock-pine species group, the second 3 signifies 51 to 75% crown closure, while the denominator signifies a young to mature stand, retarded growth with forest cover affected by exposure and shallow soils. Because symbols denoting the various map unit components are allowed to vary at random, the number of combinations, each giving new map units, is very large. Each of these map units must be evalutated before a land use decision can be made.

A semi-closed legend and simpler map symbol were chosen as the more desirable alternative for the Banff-Jasper Ecological Land Classification. Slope and selected landscape modifying processes were allowed to vary independently of the rest of the map unit concept. The symbol $\frac{PR1}{5}$ tells the reader that the mapped area falls within the concept as defined and described for PR1 and the slope (5) is 5 to 15% (Table 298 provides a definition of the concept of PR1). The limits and systematic variations of the PR1 map units are defined in the Ecosite descriptions. Designing the legend so that there are a limited number of map unit concepts, effectively limits the number of individual decisions needed when extractive, interpretive maps are produced. Unlike the situation with open legends, where each map polygon must be considered individually, the closed legend allows interpretation of the map units in the legend only, followed by mechanical labeling of the appropriate map polygons.

With reference to the second guideline, because both soils and vegetation communities are distributed over the earth's surface in a continuum, the boundaries separating mapped individuals must be fixed by definition (Rowe 1961). It was apparent during the synthesis of soil and vegetation maps of Yoho National Park into a biophysical map that slight changes in mapping concepts would have resulted in coincident soil and vegetation boundaries being defined for many of the map polygons. Map unit boundaries for soils are normally placed where the rate of change in soil properites is the greatest. For example, a soil map unit boundary may be placed where a change in slope marks the transition between a uniform, till mantled valley wall and a level floodplain. According to Hills (1976), ecosystems are characterized by a central core or node with boundaries of convenience separating the nodes. By choosing to place a soils boundary at the till-floodplain boundary it often coincides with a change in vegetation (e.g. dry to moist vegetation) and thus conveniently defines a biophysical or ecological boundary. By appropriately defining the map boundaries it is possible to keep as co-varying most of the factors that would be identified in an open multifactor legend, thus reducing the number of combinations and permutations it is necessary to recognize. Valentine and Chang (1980) have shown that in soil maps with open legends, a few indentical combinations repeat very often, while many other combinations have only one representative map polygon. This suggests that these non-repeating combinations have only one differing factor and could be accommodated by a slight change in the concept or definition of an existing repeating group without any loss of understanding. An open legend allows a more complete cataloguing of information than a closed legend, but it is improbable that it allows the development of an ecological map unit concept, which the Canada Committee on Ecological (Biophysical) Land Classification has said is desirable (Jurdant et al. 1975, Rowe 1979).

By building the legend as outlined it is possible to develop a "named" holistic, repeating map unit concept; e.g. Panorama Ridge 1 (PR1). The detailed description of PR1, including photographs and diagrams, facilitates development of this conceptual "individual" so that whenever PR1 appears, so does a complete mental landscape image. If the map unit concepts have been so developed, a lay user, by identifying from the map the symbol for a familiar ecosystem, should be able to transfer to an unfamiliar area without necessarily appreciating fully the information associated with the map unit concept. Or, in more specific terms, at site A mapped as PR1 an existing trail has remained in good condition. Therefore at site B mapped as PR1 where no trail now exists, a trail could also be expected to be stable. No reference need be made to texture, lime or other specifics.

The third guideline is that the user of an ecological land classification map has the right to assume that the information presented is of uniform intensity and reliability throughout the area covered by the map. Since the location of map unit boundaries is established by definition, it may be, for example, that the make-up of map units in the Alpine areas is more complex than in the Montane areas, but once these concepts are defined, then they should be consistently recognized throughout the map sheet regardless

of ease of access. Adopting this principle has had a significant influence on mapping procedures. When the legend was being established, biophysical delineations were chosen to correlate as closely as possible with easily recognizable landscape features in order that reliable extrapolation of lines could be accomplished using aerial photographs. If after testing the map unit concept, it was impossible to consistently identify and delineate it, then the separation was not attempted because it would not be reliable. If a separation, which could not have been extrapolated using aerial photographs, had been deemed necessary to fulfill the purpose of the inventory, then it would have been necessary to field check all of the questionable separations to maintain uniform reliability throughout the mapped area.

Since the smallest area on a map into which the map symbol $\frac{PR1}{5}$ will fit is about 0.5 to 1 cm^2, this size has been chosen as the smallest area to be delineated. A 0.5 cm^2 area on the 1:50,000 map represents about 25-40 ha (50 to 100 acres), which provides a guideline to the smallest contrasting area (as stipulated by the legend) which it was possible to delineate.

In his statement on the philosophy of Ecological Land Classification in Canada, Rowe (1979) points out the need to differentiate between classification units and mapping units. The hierarchical units Ecoregion, Ecodistrict, Ecosection, and Ecosite are defined so that once members of the ecological population are subdivided they are not recombined at a lower hierarchical level. Attempts have been made to delineate polygons named in terms of a given hierarchical level and to subdivide those large polygons, naming the smaller units in terms of a lower category in the hierarchical taxonomy (Airphoto Analysis Associates 1975). This is the hierarchical or nested mapping method. When a closed legend is used, it becomes apparent that the nested mapping approach often segregates identical landscape delineated at a low categorical level within two larger, contrasting polygons, each being defined by different taxa at the next higher category. That is, while hierarchical organization of legends according to a taxonomic system is possible, it is not practical, at least in Banff-Jasper, to organize mapping in a hierarchical fashion.

The foregoing discussion of underlying principles provides the rationale used in making the choices amongst the various methodologies that have been recorded in the literature. They provide a sense of direction where a choice between alternatives is necessary.

MAPPING METHODOLOGY

B.D. Walker, I.G.W. Corns, W.S. Taylor and G.M. Coen

METHODOLOGY OF LEGEND DEVELOPMENT

No nationally acceptable taxonomic system for biophysical or ecological classification and mapping presently exists. There are, however, guidelines (Lacate 1969, Jurdant et al. 1975, Wiken 1980) useful in developing classification procedures. Therefore, the procedure used in Banff and Jasper has been to accept the landform and soil taxonomies as they exist, develop a vegetation "community type" taxonomy and combine these into a legend which defines the mapping units. There was no attempt to develop a taxonomy for ecological classification, instead leaving that activity to the Canada Committee on Ecological Land Classification. One of the problems that this created is that there was no existing taxonomy, with defined limits, with which to develop a tentative legend for mapping. Thus, mapping and mapping legends in the Banff-Jasper Ecological Land Classification have developed through a series of approximations.

Before beginning the routine mapping, a pilot project was undertaken which defined the four hierarchical levels of biophysical taxonomy. A tentative legend and guideline for its use were established and pretyping was undertaken for the areas to be mapped. Pretyped areas were then field checked and the mapping and legend refined in accordance with the findings of the field parties. Because of the lack of a well defined or established vegetation taxonomy, much of the emphasis for the first year or two was placed on the soil and landform criteria for defining mapping unit separations. In subsequent years, mapping units were defined more and more on the basis of vegetation types as they became more firmly established. There was often a soil change concomitant with a vegetation change, although not always of sufficient significance to establish a new Ecosection definition.

Field checking was done by a team consisting of one soil scientist and one vegetation scientist, both recording their observations at a mutually acceptable point on the landscape. The site specific information was recorded directly on computer forms or on standard forms which were easily transferred to computer entry format. This allowed mechanical manipulation and comparison of the 6000 to 7000 spot observations.

Corrections to the pretyping were noted and, during the following winter, adjustments were made to the lines on the aerial photographs

to finalize the map units. Each year the legend was readjusted to account for the changes in map unit concepts which developed over the summer season.

Mapping was done initially on 1:66,000 and 1:50,000 scale, black and white aerial photographs and later transferred to 1:50,000 base maps. Initial landscape stratification involved establishing Ecoregion, Ecoregion subunit, and genetic material unit boundaries within an area (Plates 82, 83). Superimposition of more detailed soil and vegetation information, organized at the Ecosite level in the Banff-Jasper Ecological Land Classification, produced the final mapping level with polygons named at the Ecosite level and modified by slope classes (Plate 84). In some cases, minor boundary adjustments of initial stratifications were necessary to accomplish the final step.

At the Ecosection and Ecosite levels, the mapping does not follow the nested mapping approach discussed previously. That is, the land is not stratified into polygons representing the Ecosection level (Plate 84). Further, the component parts (i.e. Ecosites) constituting an Ecosection do not necessarily exist contiguously on the landscape. For example, polygons mapped as PR1, PR2, PR3, PR4, and PR6 at the Ecosite level, frequently do not share boundaries to form a larger polygon called PR, representing the Ecosection level. Plate 84 illustrates this approach. Tracts mapped as PR2 and PR4 are generally isolated from each other and from PR1 and PR3. The PR6 Ecosite does not occur in Plate 84 and PR1 and PR3, in this instance, share a boundary. Nevertheless, Ecosystem entities (i.e. the aggregate that is PR) exist conceptually and the mapping legend is therefore hierarchical.

To complete the "biophysical" requirements of the inventory, wildlife observations were made by the Canadian Wildlife Service team during the following season to characterize the established map units. By characterizing "habitats" it was felt that predictive capability would be developed with relation to animals (or communities of animals) and Ecosite concepts. The iterative process of re-evaluation of Ecosite concepts, relative to the experience of the wildlife sector, allows for the identification of Ecosite concepts which would not have been justified or established on the basis of soils and vegetation parameters alone. The final ecological compilation presents Ecosite concepts which are defined not only in terms of their landform, soil, and vegetation components but which present concomitant wildlife parameters as well. The detailed methodology for wildlife inventory is presented in Volume III.

DESIGN OF THE MAPPING LEGEND

The current Ecological Land Classification guidelines (Wiken 1980) were taken as the starting point for developing the mapping legend used for the Banff-Jasper Ecological Land Classification. To develop the taxonomy, class limits should have been defined for each of the hierarchical levels and taxa within those levels. This would have resulted in a matrix of "pigeon holes" into which the ecological universe could be partitioned. Since only a portion of the ecological universe is present in Banff and Jasper it was impossible to develop credible taxon limits except for portions of the taxonomy. Thus, a mapping legend was developed with limits separating mapping concepts coincident to probable taxon limits wherever possible. The following discussion of Ecoregions, Ecosections, and Ecosites is in the context of how these taxonomic hierarchical levels influenced the mapping legend. Ecodistrict separations were not undertaken in the development of the legend.

ECOREGIONS

Three major Ecoregions (ecological zones) are represented in Banff and Jasper National Parks: Montane, Subalpine, and Alpine (Fig. 21). The Ecoregion is the broadest level of ecosystem classification used in this study and is based primarily upon differences in vegetation physiognomy and species composition which reflect differences in macroclimate. An Ecoregion, as used here, is conceptually similar to the zone of Daubenmire (1968) and La Roi (1975), the biogeoclimatic zone of Krajina (1965) and Kojima (1980), the biophysical region of Lacate (1969) and the Ecoregion of Wiken (1980) and Strong and Leggat (1981).

Montane Ecoregion

The Montane Ecoregion is the least extensive areally but is the most intensively used by man and of crucial importance to wildlife. In Banff, it extends from the Trans-Canada Highway east gate, upstream along the Bow valley to Johnston Creek. (Fig 21). A somewhat smaller area of Montane in Banff extends from the David Thompson Highway east gate up the North Saskatchewan and Howse rivers to Glacier Lake to the west, Arctomys Creek to the north, and to 5 km south of Saskatchewan Crossing. Modal elevations of the Montane Ecoregion in Banff range from about 1350 m, where the Bow River leaves Banff, to about 1500 m on north aspects and 1650 m on steep south exposures. These elevational ranges are similar for the Saskatchewan Crossing area with the lowest elevations being about 1400 m where the North Saskatchewan River leaves Banff.

The Montane Ecoregion in Jasper is more extensive than in Banff and is restricted to the Athabasca River valley and the lower parts of its tributaries (Fig. 21.) It extends from the Highway 16 east gate, upstream along the Athabasca River, including the lower reaches of the Fiddle, Rocky, Snake Indian, Snaring, Maligne, Astoria, and Whirlpool Rivers and Mosehorn Creek, to its southern extent near Sunwapta Falls. To the west, the Montane Ecoregion follows the Miette River valley to Jasper's West Gate. Modal elevations of the Montane in Jasper range from about 1000 m at the East Gate to about 1300 m on north aspects and 1400 m on steep south exposures (Fig. 22). An examination of Fig. 22 reveals that the Ecoregions of Banff are somewhat more compressed elevationally, than is the case in Jasper. Environmental factors, climatic or otherwise, that may account for this phenomenon are not apparent.

The vegetation of the Montane Ecoregion has developed in response to warm, dry air masses from central British Columbia moving eastward through the Vermilion, Kicking Horse, Howse and Yellowhead Passes into the Bow, North Saskatchewan and Athabasca valleys. Warm winter winds (chinooks) result in intermittent snow cover. Dry portions of the Montane on the valley bottoms and lower valley walls (e.g. AT3, HD4 and TA2 Ecosites) are characterized by the junegrass-pasture sage-wild flax (H6) v.t., while dry glacial and glaciofluvial slopes such as the Norquay Ecosection may have mature Douglas fir/hairy wild rye (C1) v.t. or where fire has been more frequent, lodgepole pine/juniper/bearberry (C3). More mesic situations on the valley walls and northerly aspects in the Montane are characterized by the white spruce-Douglas fir/feathermoss (C5) v.t. or the lodgepole pine/buffaloberry/showy aster (C6) v.t. and the lodgepole pine/buffaloberry/twinflower (C19) v.t.

Soils of mesic to subxeric, stable localities in the Montane Ecoregion are dominantly Eutric Brunisols, many exhibiting weak luvisolic tendencies. Genetically related Gray Luvisols are codominant on morainal landforms under similar moisture conditions. Regosolic soils are associated with active or recently active erosion and deposition. Various wet soils (Gleysolic and Organic soils) occur on wet terrain.

Subalpine Ecoregion

The Subalpine Ecoregion is cooler and moister than the Montane (Tables 2 and 3), occurs at elevations above the Montane Ecoregion and below the treeless Alpine and is characterized by continuous winter snow cover. The Subalpine Ecoregion is mainly forested, with Engelmann spruce and subalpine fir characteristic of mature forests. Lodgepole pine dominates successional forests but herb and shrub-dominated communities also occur, especially on wet terrain. The Subalpine Ecoregion is separated into Lower and Upper Subalpine portions on the basis of vegetation development and stand structure, reflecting differences in macroclimate.

The Lower Subalpine in Banff extends from approximately 1500 m to 1950 m on north aspects and from 1650 to 2050 m on steep south exposures. In Jasper elevations are 1300 to 1800 m on north aspects and 1400 to 1900 m on steep south exposures. The Lower Subalpine encompasses most of the closed forest (crowns separated by <2X crown width and >15-20% cover) of Banff and Jasper. In the Main Ranges, common lodgepole pine dominated v.t.s are lodgepole pine/buffaloberry/showy aster (C6), lodgepole pine/buffaloberry/twinflower (C19), lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/false azalea/grouseberry (C20). On sites with mature forest, common v.t.s are Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/false azalea (C14). In the Front Ranges, the moister v.t.s mentioned above, notably lodgepole pine/buffaloberry/grouseberry (C18), lodgepole pine/false azalea/grouseberry (C20), and Engelmann spruce-subalpine fir/false azalea (C14) are less prevalent. Several v.t.s, reflecting a drier climate found in the Front Ranges and occurring less frequently in the Main Ranges, are lodgepole pine/Labrador tea (C29), Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30), Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31), Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) and willow/hairy wild rye (S12).

Soil variability is greater in the Lower Subalpine compared to the Montane. Mesic, stable localities on calcareous parent materials are dominated by Eutric Brunisols. Gray Luvisols are subdominant at lower elevations and on southerly aspects with pine forest. Dystric Brunisols have similar drainage regimes but occur on noncalcareous parent materials. Podzolic soils occur sporadically and are associated with Eolian material B veneers on cool, moist slopes with Engelmann spruce-subalpine fir vegetation. These are most abundant in western Banff and southwestern Jasper. Regosolic soils are associated with active or recently active erosion and deposition. Various wet soils, including Gleysolic, Organic, gleyed Brunisolic, and gleyed Podzolic soils, are associated with wet terrain. Lower Subalpine grassland soils (Regosols and Brunisols) in eastern Banff and Jasper often have thick (>10 cm) organo-mineral (Ah) horizons, but some of these may also be classified as Chernozemic soils (refer to Chapter II, Soils).

The Upper Subalpine portion of the Subalpine Ecoregion is characterized by open forests (crowns separated by 2-5X crown widths and <15-20% cover) and is transitional between the Lower Subalpine closed forests and the treeless Alpine. Upper Subalpine includes the krummholz ecotone which some authors (e.g. La Roi 1975) place in the Alpine. Compared with the Lower Subalpine, the Upper Subalpine climate is cooler and wetter with greater precipitation, later snow melt, and a shorter growing season. The Upper Subalpine in Banff extends from approximately 1950 to 2250 m on north aspects and from 2050 to 2350 m on steep south aspects. In Jasper, elevations are 1800 to 2150 m on north aspects and 1900 to 2250 m on south exposures. Vegetation is predominantly open forest dominated by Engelmann spruce and subalpine fir with representative v.t.s on cool, high elevation sites being Engelmann spruce-subalpine fir/heather (O10) and Engelmann spruce-subalpine fir/valerian-fleabane (O9). Closed forests such as Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), Engelmann spruce-subalpine fir/grouseberry (C15) and, in southern Banff, subalpine larch-subalpine fir/grouseberry-everlasting (C23) occur at lower elevations within the Upper Subalpine, often on warmer south aspects, particularly in the Main Ranges and near the Continental Divide. In the Front Ranges of eastern Banff and Jasper, closed forest v.t.s such as Engelmann spruce-subalpine fir/rock willow/white mountain heather (C24), Engelmann spruce-subalpine fir/heather/feathermoss (C34), Engelmann spruce/hairy wild rye (C33) and hairy wild rye-junegrass-bearberry (H14) grasslands are more likely to occur, in response to a drier climate with less snowfall.

Soils of the Upper Subalpine are similar to those of the Lower Subalpine. Mesic, stable localities on calcareous parent materials are dominated by Eutric Brunisols. Dystric Brunisols have similar drainage regimes but occur on noncalcareous parent materials. Podzolic soils occur sporadically and are associated with altered, medium textured Eolian material B veneers. These are most abundant in western Banff and southwestern Jasper. Regosolic soils are associated with active or recently active erosion and deposition. Soils of the Upper Subalpine-Alpine ecotone, dry shrubland, and grassland areas usually have organo-mineral (Ah) horizons, in many cases exceeding 10 cm in thickness (Melanic Brunisols, Sombric Brunisols, and Humic Regosols). Some of these soils on steeply sloping grasslands may also be classed as Chernozemic soils (refer to Chapter II, Soils). Cryosolic soils are common on steep, forested (spruce-fir), northerly aspects in the Front Ranges subprovince on genetic material derived from Mesozoic strata. Various wet soils, including Gleysolic, Organic, gleyed Brunisolic, and gleyed Podzolic soils, are associated with wet terrain.

Alpine Ecoregion

The treeless Alpine Ecoregion occurs above the Upper Subalpine and reflects a cold, harsh climate (ET - Koeppen system; Trewartha 1957). Alpine vegetation typically forms a complex, fine-scale mosaic in which microclimate variations are reflected by marked changes in dominant species and v.t.s. Important microclimatic factors include aspect, wind exposure, time of snowmelt, snow depth, soil moisture and soil physical - chemical characteristics. The most common v.t.s in the Main Ranges and near the Continental Divide are heather-everlasting (L5) in high snowfall areas, mountain avens-snow willow-moss campion (H1) on wind exposed sites and white mountain heather-mountain avens-snow willow (L4) on moderately deep snowbed sites. In the Front Ranges in eastern Banff and Jasper, the heath-dominated v.t.s are less prominent with the H1 v.t. assuming greater importance. In addition, a characteristic Front Range v.t. mountain avens-kobresia-bearberry (H4) occurs. The highest elevation communities are usually saxicolous lichen (H12) tundra on rock and shallow soils. The H12 v.t. is best developed on acidic rocks especially quartzites in the Main Ranges.

Alpine soils, like vegetation, form a complex, fine-scale mosaic. Their distribution is governed by depth, distribution, kind and stability of parent materials, exposure, and depth of organo-mineral (Ah) horizon accumulation across the landscape. Brunisolic soils are abundant. Eutric (<10 cm of Ah) and Melanic (>10 cm of Ah) Brunisols are associated with stable, calcareous, parent materials under mesic moisture conditions. Dystric (<10 cm Ah) and Sombric (>10 cm of Ah) Brunisols are associated with stable, noncalcareous, parent materials under similar moisture conditions. Podzolic soils occur sporadically and are associated with Eolian material B veneers. These are most abundant in western Banff and southwestern Jasper. Active and recently active geomorphic processes (both erosional and depositional) are important in the Alpine Ecoregion, hence Regosolic soils, with varying thicknesses of Ah horizon, are abundant. These processes include wind erosion and deposition, colluviation, fluvial activity, solifluction, and cryoturbation. Shallow soils are often Regosolic and grade to nonsoil on high elevation, feral Alpine slopes. Wet soils are important locally.

Alpine subunits cannot be delineated even at a 1:50,000 scale, so the Alpine Ecoregion of this report includes the lower, middle and part of the upper subzones of La Roi (1975).

Much of the upper subzone is frequently mapped as Rockland (R) or Colluvial Rubble (CR).

ECOSECTIONS

Ecoregions are divided into 55 Ecosections. The Ecosections are named after geographic features, and assigned a two letter, connotative symbol. The limits of the classes of Ecosections are based on broad differences in genetic materials and drainage classes as reflected by landform features. Variations in genetic materials that result in the establishment of Ecosections are glacial (including morainal and ice contact stratified), glaciolacustrine, glaciofluvial, fluvial (including fluviolacustrine), colluvial, landslide, eolian, and residual (Table 95). These eight classes are subdivided into two groups based on moisture regime. Wet terrain includes land areas dominated by soils classed as poorly drained and very poorly drained (C.S.S.C. 1978a), i.e. hygric to hydric site moisture regimes. Non-wet terrain includes land areas dominated by soils classed as moderately well drained and drier, i.e. mesic to xeric moisture regimes. Land areas dominated by imperfectly drained soils are placed in either the wet or non-wet group, depending upon the moisture regime of the predominant vegetation and associated soils and vegetation.

For pragmatic reasons, further subdivision of wet terrain is inappropriate. Where necessary land areas dominated by non-wet terrain are further subdivided according to one or more of the following criteria:

1. Calcareous versus noncalcareous genetic materials;
2. Three genetic material textural groups, two of which are used for Ecosection separations within certain genetic material classes;
3. Five soil-vegetation classes reflecting geomorphic activity and/or mesoclimatic differences;
4. Landform surface expression.

The first two criteria are also used in making genetic material unit separations described in the Geomorphology section (Chapter I) and summarized in Table 6. Table 96 shows, as an example, the organization of Lower Subalpine Ecosections associated with glacial genetic materials.

Calcareous Versus Noncalcareous Genetic Materials.

Reaction and calcareousness of soils were described using 6 classes (C.S.S.C. 1978a) or combinations thereof. In the Banff-Jasper Ecological Land Classification legend two groups, noncalcareous and calcareous, are used for Ecosection separations. Borderline situations, such as weakly calcareous materials or materials with lime at considerable depth from the soil surface, are placed in either class, the decision being influenced by factors such as extent, pH of solum, texture, major lithological source and vegetation. Some genetic materials of limited extent or heterogeneous chemical characteristics are not further subdivided at the Ecosection level.

Table 95 Organization of Ecosections by Ecoregion and genetic material classes.

Genetic Material	Ecoregions and Subdivisions			
	Montane	Subalpine		Alpine
		Lower	Upper	
Residual	-	BZ	CP	HE
Landslide	GA	IB	BP	-
Colluvial	-	FV, SB	EN, WH, WF	BS, RD, TK
Glacial (morainal plus ice contact stratified)	PT, NY	BK, BY, CA, CV*, GT, ML, PR, (TZ)‡, WW †	AZ, EG, LV, PL, SF, SX*, TR	EF, JN, MP
Glaciofluvial	AT	BV, (TZ)	NG	-
Fluvial (including fluviolacustrine)	FR, HD, VL*	AL, HC*, PP, VD	CN, MQ, NT*	KA
Glaciolacustrine	NH*, RK	MC*, SP	-	-
Eolian	DV, TA	-	-	-

* Dominantly wet terrain

† Refer to Table 96

‡ The TZ Ecosection is defined as being associated with two genetic material classes

Table 96 Example of Ecosection separations with glacial genetic materials (refer to Table 95) in the Lower Subalpine Ecoregion.

Glacial Genetic Materials of the Lower Subalpine								
Dominantly Wet Terrain	Dominantly Non-wet Terrain							
	Noncalcareous			Calcareous				
	Medium Texture	Coarse Texture		Dominantly Medium Texture

CV	CA	ML	(TZ)*	WW	GT	PR†	BY	BK

* Subdominant genetic material is noncalcareous, coarse textured glaciofluvial

† Refer to Table 97

Genetic Material Textural Classes

Textural classes (C.S.S.C. 1978a) can be combined in a variety of ways for various purposes. In the Banff-Jasper survey, three broad textural groups were recognized:

a. Coarse textured genetic materials, derived mainly from medium and coarse grained clastic bedrock, usually have more than 60% sand and include the sand, loamy sand, and part of the sandy loam textural classes;

b. Medium textured materials, derived mainly from medium to fine grained carbonate and clastic bedrock, most commonly including the loam, silt loam, and part of the sandy loam textural classes;

c. Fine textured materials, deposited primarily by still water sedimentation, including clay loam, silty clay loam, and silty clay textural classes.

Only the coarse and medium textured groups are used for making separations at the Ecosection level and then, only for genetic materials which have textural characteristics related to the lithological sources (e.g. morainal material, Table 96), provided that each group is of sufficient areal extent and homogeneity to be separated. Textural characteristics of glaciofluvial, fluvial, glaciolacustrine, and eolian genetic materials are a function of the depositional agents. Therefore, further separation is unnecessary at the Ecosection level. The fine textured group applies to glaciolacustrine sediment and to fluviolacustrine sediment generally contained within fluvial landforms. Hence, it is more useful for making separations at the Ecosite level rather than the Ecosection level. Fine textured genetic materials derived from fine grained, calcareous, clastic bedrock do occur (e.g. fine textured morainal material) but are of limited areal extent and are not separated. Stratified materials such as fluvial (including fluviolacustrine) deposits were not subdivided into Ecosections according to the above textural criteria because of the wide textural variation within small delineations.

Soil-Vegetation Classes Reflecting Geomorphic Activity and/or Mesoclimate

Certain differences in soil and vegetation development are thought to reflect mesoclimatic differences or recent geomorphic activity and thus are used to make Ecosection separations. The five classes are defined as follows:

a. Land areas dominated by Regosolic soils and other soils with weak profile development (e.g. WW Ecosection, Table 96). These areas are influenced by recent soil erosion or deposition. A wide variety of vegetation types are associated with Regosolic soils;

b. Land areas dominated by Brunisolic soils with thin sola and associated Regosolic soils (e.g. GT Ecosection, Table 96). Both recent soil disturbances (erosion or deposition) and mesoclimatic factors (mainly aspect) influence soil and

vegetation development. Associated vegetation types are predominantly mesic to subxeric lodgepole pine forest, Douglas fir forest, grassland, and dry to moist shrubby vegetation;

c. Land areas dominated by Brunisolic soils with associated Luvisolic or luvisolic-like soils (e.g. PR Ecosection, Table 96). Associated vegetation types are mostly mesic lodgepole pine forests;

d. Land areas dominated by Brunisolic and Podzolic soils, generally found above 1500 m and in moister areas (e.g. BY Ecosection, Table 96). Associated vegetation types are predominantly mesic to subhygric Engelmann spruce-subalpine fir forests;

e. Land areas dominated by Cryosolic soils with associated Engelmann spruce-subalpine fir forest (i.e. SF Ecosection, Table 95).

The first two classes are related to current or recent geomorphic activity, in particular fluvial and colluvial materials. Class "a" does not strongly reflect mesoclimatic influences. In both cases, vegetation types are more likely to reflect mesoclimatic differences than are the soils. On steep colluvial slopes, in order to emphasize the instability of materials, Ecosection distinctions were not made among classes "a" through "e" above.

Classes "b" to "e" represent a subdivision of the mesoclimatic continuum from warm and dry to cool and moist into three groups. The continuum results from orographic change (east to west), aspect differences (southerly versus northerly exposures), and/or altitudinal change (lower to higher). Some of the separations into the five classes may not clearly reflect mesoclimatic differences. Parent material characteristics are particularly important in some cases. Examples are the presence of Eolian material B related to the occurrence of Podzolic soils and the influence of Mesozoic strata on the development of Cryosolic soils.

Landform Surface Expression Producing a Dry >Wet Landscape

Most parent material changes are accompanied by landform surface expression changes and thus, few Ecosection separations are based on landform surface expression alone. Hummocky glacial landforms producing a dry > wet landscape pattern are a major exception. The distinct repeating dry and wet pattern resulting in complex soil-vegetation relationships (as in the BK Ecosection, Table 96) is sufficiently different from the uniformly sloping dry pattern of inclined glacial landforms (as in the PR Ecosection) to warrant separation at the Ecosection level. The dry and wet components are distinct but cartographically inseparable. This criterion applies, at the Ecosection level, only to glacial landforms of the Lower Subalpine where this complex landscape is most extensive.

As with any criteria defining cartographic concepts, individuals falling close to class boundaries may be more like each other than like the different central concepts to which they belong. Thus, cartographic separations involving a continuum always necessitate some arbitrary decisions as to which class a given individual may belong. The guidelines above are considered reasonably precise with regard to the central concepts of the classes and have resulted in decisions which produce a useful organization of the natural phenomena being mapped.

ECOSITES

The 55 Ecosections have been further separated into 124 Ecosites and named as numerical subdivisions of the Ecosection name, e.g. the Ecosection name PR is subdivided by numerals to give PR1, PR2, PR3, etc. The subdivisions are made on the basis of physiognomic and, to some extent, floristic differences in vegetation as well as differences in soil parameters. Factors limiting the implementation of these criteria or the degree to which they are used include scale of mapping, ease of photographic interpretation, and areal extent of the proposed Ecosite definition.

Generally, subdivision of Ecosections into Ecosites is based on the following criteria.

Physiognomic Groupings

Land areas with differing physiognomic groupings of vegetation that were not previously separated at higher levels in the mapping hierarchy are separated when they differ with respect to the following:

a. Land areas having closed forests (see definition in vegetation section, Chapter III) as the predominant vegetation physiognomy;

b. Land areas having open forests (see definition in vegetation section, Chapter III) as the predominant vegetation physiognomy;

c. Land areas having shrubs as the predominant vegetation physiognomy;

d. Land areas having low shrubs and herbs as the predominant vegetation physiognomy;

e. Land areas having herbs as the predominant vegetation physiognomy.

Habitat Grouping

Land areas, not previously separated at the Ecosection level, with selected vegetation type groupings useful in the identification of wildlife habitat (D. Karasiuk, G. Holroyd, CWS, Edmonton, personal communications) are separated as follows:

a. Land areas having poplar forest as the predominant vegetation;
b. Land areas having lodgepole pine forest as the predominant vegetation;
c. Land areas having lodgepole pine/buffaloberry forest as the predominant vegetation;
d. Land areas having Engelmann spruce-subalpine fir forest as the predominant vegetation;
e. Land areas near timberline having a mosaic of heath tundra plus scattered Engelmann spruce-subalpine fir trees, tree islands, or krummholz as the predominant vegetation;
f. Land areas having subalpine larch forests as the predominant vegetation;
g. Land areas having avalanche complex (shrubs and herbs) as the predominant vegetation.

Genetically Similar Soil or Landform Parameters.

Soil parameters not previously used to make separations at the Ecosection level and not necessarily identified with covarying vegetation type or physiognomy differences result in the following separations:

a. Land areas dominated by imperfectly drained soils (Gleyed subgroups) are separated from land areas having dominantly moderately well drained and drier soils;
b. Land areas dominated by Brunisolic soils are separated from land areas having dominantly Brunisolic-Regosolic soils or Brunisolic-Podzolic soils. Such separations are not appropriate at the Ecosection level because the land areas involved are of limited areal extent and because pedogenic differences are minor;
c. Land areas dominated by ice contact stratified drift are separated from land areas dominated by morainal deposits.

Complex Map Units

Land areas comprised of two distinct but cartographically inseparable soil-vegetation components, not previously used to make separations at the Ecosection level, are separated as follows:

a. Land areas comprised of distinct northerly and southerly aspects, as reflected by major differences in soil and vegetation are separated from land areas comprised mainly of either end member;
b. Land areas comprised of a distinct wet and dry pattern of soils and vegetation are separated from land areas comprised mainly of either end member;
c. Land areas having vegetation type distributions controlled by shallow parent materials, involving lithic and non-lithic or non-soil and lithic soil patterns, are separated from land areas with deeper soils and a comparatively uniform vegetation type cover.

Table 97 gives an example of the subdivision of an Ecosection into its component Ecosites. Soil and vegetation differences used to define Ecosites are considered insufficient in magnitude or kind to warrant separations at the Ecosection level. An attempt was made to define repeating natural Ecosite concepts so that differences among central concepts are of equal magnitude. Having established this statement as a model, it is very difficult to evaluate whether the diverse differentiating criteria, in aggregate, give the desired results.

Table 97 Example of Ecosite separations within an Ecosection.

Ecosite	Landform*	Soils	Vegetation†
PR1	Till C blankets overlying inclined bedrock	Eutric Brunisols > Gray Luvisols	lodgepole pine/false azalea, lodgepole pine/feathermoss, lodgepole pine/Labrador tea
PR2	Till C blankets overlying inclined bedrock	Eutric Brunisols > Gray Luvisols	logepole pine/buffaloberry
PR3	Till C blankets overlying inclined or hummocky bedrock, hummocky Till C	gleyed Eutric Brunisols > gleyed Gray Luvisols	lodgepole pine forest
PR4	inclined Till C and Ice Contact Stratified Drift B	Northerly aspects: Eutric Brunisols Southerly aspects: Eutric Brunisols > Gray Luvisols, Regosols	Northerly aspects: Engelmann spruce - subalpine fir forest Southerly aspects: logepole pine forest
PR6	Ice Contact Stratified Drift B blankets overlying inclined or hummocky bedrock, hummocky Ice Contact Stratified Drift B	Eutric Brunisols > Gray Luvisols	lodgepole pine forest

* **Landform** —Specific genetic material units are presented; refer to Geomorphology section, and Table 6.

† **Vegetation** —In order to differentiate PR1 from PR2, vegetation is presented at a more detailed level of description than for the other PR Ecosites.

ECOSECTION/ECOSITE DESCRIPTIONS

B. D. Walker, W. S. Taylor, D. T. Allan, and R. E. Wells

INTRODUCTION

A comprehensive discussion of each ecological mapping concept used in the Banff-Jasper Ecological Inventory is provided in this section. The Ecosection descriptions are arranged in alphabetical order for ease of referencing. Tables, figures and plates are provided to illustrate the Ecosite concepts. Fig. 29 provides a legend identifying the components of the schematic cross section diagrams.

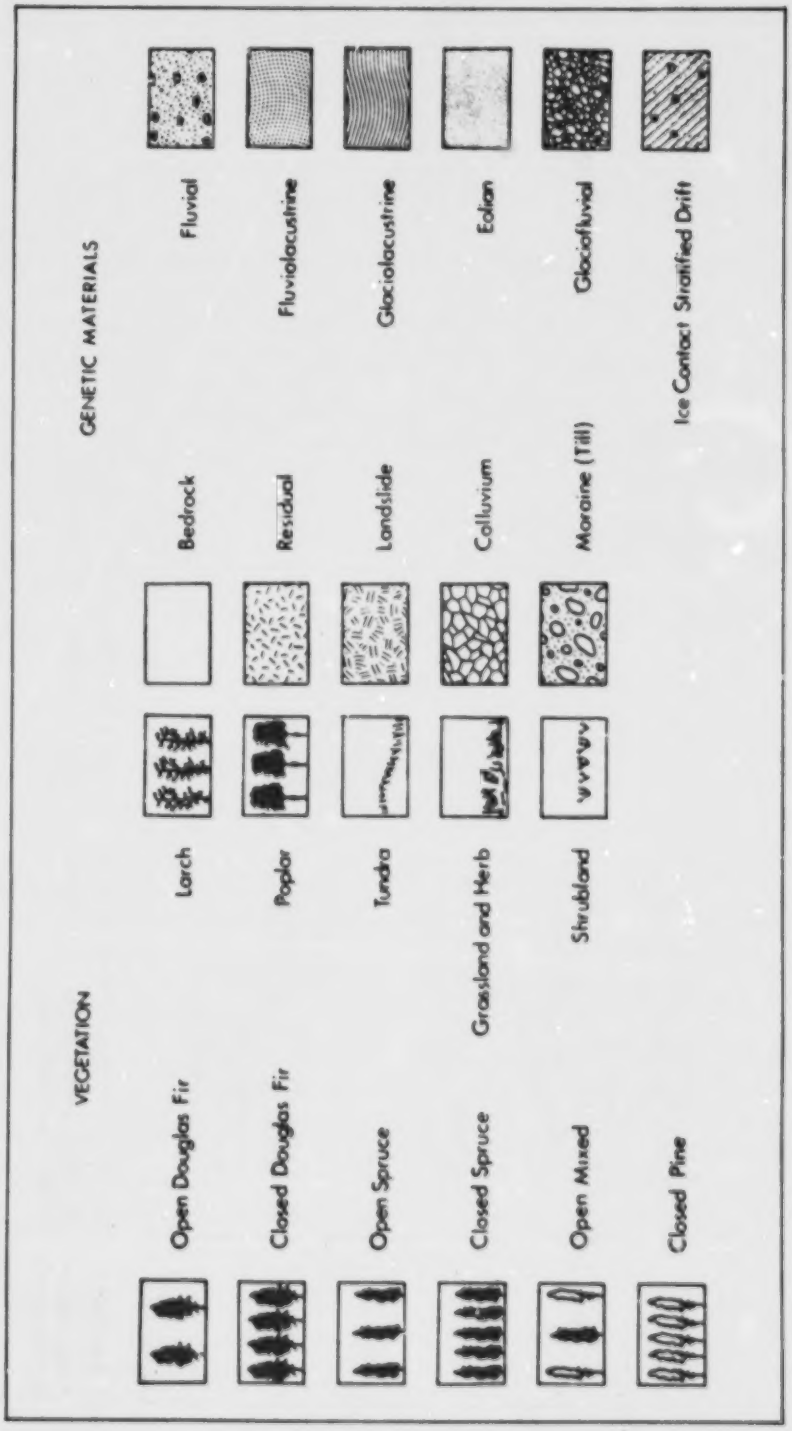

Figure 29 Legend identifying components of the schematic cross section diagrams illustrating the Ecosite descriptions.

AL - ALTRUDE ECOSECTION

The Altrude Ecosection encompasses relatively stable fluvial landforms comprised of calcareous, coarse, stratified fluvial material (Fluvial material B) within the Lower Subalpine portion of the Subalpine Ecoregion. Brunisolic soils associated with lodgepole pine and Engelmann spuce-subalpine fir forests dominate this Ecosection. The AL Ecosection occupies lower slopes and valley floors of main and tributary valleys in both parks.

Two Ecosites are differentiated (Table 98) within the Altrude Ecosection based on vegetational differences.

Table 98 General features of the Altrude (AL) Ecosites.

Ecosite	Landform	Soils	Vegetation
AL1	Fluvial material B; fan, apron	Eutric Brunisol	lodgepole pine forest
AL2	Fluvial material B; fan, apron	Eutric Brunisol	Engelmann spruce-subalpine fir forest

AL1 - ALTRUDE 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, AL1, occurs on relatively stable fluvial fans and aprons consisting of calcareous, coarse, stratified fluvial material (Fluvial material B) and is dominated by well drained Orthic and Eluviated Eutric Brunisols and the lodgepole pine/buffaloberry/twinflower (C19) v.t.

Geomorphology

The AL1 Ecosite occurs on relatively stable fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Land mapped as AL1 commonly has linear slopes between 2% and 45%. Surficial veneers of altered, medium textured eolian material (Eolian material B) thinly mantle those AL1 tracts with the oldest surfaces especially in western Banff and southwestern Jasper. Irregular surfaces produced by channeling (Eroded modifier, C.S.S.C. 1978b) are a common feature of the AL1 Ecosite. Other fluvial landforms occasionally found in AL1 tracts include veneers, blankets and level plains. Veneers and blankets of Fluvial material B usually overlie morainal landforms or, occasionally, colluvial aprons and fans, glaciofluvial fans and terraces or glaciolacustrine blankets.

Soils

The AL1 Ecosite is characterized by well drained Orthic and Eluviated Eutric Brunisols. The degree of development of these soils reflects geomorphic stability. Narrow strips dominated by Orthic and Cumulic Regosols occur along present and recently abandoned stream channels. These soils reflect a more active environment and may be subject to erosion or flooding during spring run-off and periods of high precipitation. Eutric Brunisols with Btj horizons, Brunisolic Gray Luvisols and Orthic Gray Luvisols were found on a few tracts of AL1 but Luvisolics occur very rarely. The following pedon description (Table 99) illustrates an Orthic Eutric Brunisol of the AL1 Ecosite.

Table 99 Pedon (Alberta 1974 No. 105) description of an Orthic Eutric Brunisol of the AL1 Ecosite.

CLASSIFICATION: TAXONOMIC SYSTEM OF THE YEAR 1978, SUBGROUP: ORTHIC EUTRIC BRUNISOL. SOIL MAP UNIT: NOTATION: AL1.

Vegetation

The AL1 Ecosite is dominated by the mesic lodgepole pine/buffaloberry/twinflower (C19) v.t. Lodgepole pine/buffaloberry/showy aster (C6) and lodgepole pine/buffaloberry/grouseberry (C18) are accessory v.t.s. Inclusion of v.t.s lodgepole pine/feathermoss (C11), lodgepole pine/false azalea/grouseberry (C20) and lodgepole pine/Labrador tea (C29) also occur on AL1. These v.t.s commonly have spruce in the understory. V.t. lodgepole pine/dwarf bilberry (C9) is found on AL1 in southern Banff. Minor amounts of spruce dominated v.t.s may also occur in small patches, especially associated with Regosolic soils. Table 100 and Plate 85 represent the C19 v.t. commonly found on AL1 Ecosites. This vegetation plot was described on a fluvial fan approximately three km east of the soil pedon site.

Discussion

The AL1 Ecosite most closely resembles the Pipestone 1 (PP1), Verdant 2 (VD2), and Fireside 1 (FR1) Ecosites in terms of landform and vegetation. The PP1 Ecosite is dominated by Orthic and Cumulic Regosols that reflect a more active geomorphic environment. The VD2 Ecosite occurs on fluvial landforms consisting of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and is dominated by acidic soils, and FR1 is separated because it occurs in the Montane Ecoregion.

Mapped tracts designated as AL1A have 20 to 50% of their area modified by snow avalanching.

AL2 - ALTRUDE 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, AL2, occurs on fluvial fans and aprons consisting of calcareous, coarse, stratified fluvial material (Fluvial material B). The AL2 Ecosite is dominated by well to moderately well drained Orthic and Eluviated Eutric Brunisols associated with Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.s.

Geomorphology

The AL2 Ecosite occurs on fluvial fans and aprons consisting of calcareous, coarse, stratified fluvial material (Fluvial material B). Land mapped as AL2 commonly has linear slopes between 2% and 45%. Surficial veneers of altered, medium textured eolian material (Eolian material B) thinly mantle those AL2 tracts with the oldest surfaces, especially in western Banff and southwestern Jasper. Irregular landform surfaces produced by channeling is a common feature. Other fluvial landforms occasionally found in AL2 tracts include veneers, blankets and level plains. Veneers and blankets of Fluvial material B usually overlie morainal landforms or, occasionally, colluvial aprons and fans, glaciofluvial fans and terraces, or glaciolacustrine blankets.

Soils

The AL2 Ecosite is dominated by well to moderately well drained Orthic and Eluviated Eutric Brunisols. The degree of development of these soils reflects geomorphic stability. Narrow strips dominated by Orthic and Cumulic Regosols occur along present and recently abandoned stream channels. These soils reflect a more active environment and may be subject to erosion and flooding during spring run-off and periods of high precipitation. Eutric Brunisols with Btj horizons and Brunisolic Gray Luvisols were found on a few AL2 polygons but Luvisolics occur very rarely. A pedon illustrating Orthic Eutric Brunisols of the AL2 Ecosite is described in Table 101 and shown in Color Plate 1.

Table 101 Pedon (Alberta 1978 No. 216) description of an Orthic Eutric Brunisol of the AL2 Ecosite.

Vegetaton

The AL2 Ecosite is dominated by mesic Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.s. The C13 v.t. occurs more often than C31 on AL2. However, many AL2 tracts located in eastern portions of both parks are dominated by C31. Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) occurs as an accessory on some AL2 tracts located in the Front Ranges subprovince. Small amounts of lodgepole pine/feathermoss (C11), Engelmann spruce-subalpine fir/false azalea (C14), white spruce/buffaloberry/fern moss (C26) and Engelmann spruce/horsetail/feathermoss (C32) v.t.s may also be found on some AL2 tracts but occur rarely. Table 102 and Plate 86 illustrate the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. commonly found on AL2.

Table 102 Stand (JC8081) illustrating the Engelmann spruce-subalpine fir / feathermoss (C13) v.t. of the AL2 Ecosite.

Discussion

The Altrude 2 Ecosite most closely resembles the Pipestone 3 (PP3) and Verdant 1 (VD1) Ecosites in terms of landform and vegetation. The PP3 Ecosite differs because it is dominated by Orthic and Cumulic Regosols that reflect a more active geomorphic environment. The VD1 Ecosite is different because it occurs on fluvial landforms comprised of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and is dominated by acidic soils.

Mapped tracts designated as AL2A have 20% to 50% of their area modified by snow avalanching.

AT - ATHABASCA ECOSECTION

The Athabasca Ecosection occurs on calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Montane Ecoregion. Eutric Brunisols are the dominant soils, with the vegetation being lodgepole pine forest, or a pattern of this forest and dry grassland.

The AT Ecosection is found frequently and with greatest extent on broad valley floors and lower benchland throughout the Montane in Banff and Jasper. Extensive examples are mapped along the floor of the Athabasca River valley from the Snaring to the Sunwapta Rivers.

Two Ecosites (AT1, AT3) are defined mainly by differences in vegetation. Table 103 outlines general features of the AT Ecosites.

Representations of AT1 on the landscape are presented in Figs. 47 and 50. The AT3 Ecosite occupies similar landscape positions.

Landform genesis of the AT Ecosection can be compared to the presently actively aggrading glaciofluvial landform of the Pipestone 4 (PP4) Ecosite.

Table 103 General features of the Athabasca (AT) Ecosite.

Ecosite	Landform	Soils	Vegetation
AT1	Glaciofluvial material B; terrace	Eutric Brunisol	lodgepole pine forest
AT3	Glaciofluvial material B; terrace	Eutric Brunisol	dry grassland > lodgepole pine forest

AT1 - ATHABASCA1 ECOSITE

Ecosite Concept

The AT1 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Montane Ecoregion. Soils are Orthic and Eluviated Eutric Brunisols and vegetation is lodgepole pine/juniper/bearberry (C3), lodgepole pine/buffaloberry/showy aster (C6) and lodgepole pine/buffaloberry/twinflower (C19). The AT1 Ecosite is the more extensive of the two AT Ecosites.

The AT1 Ecosite is found on floors and lower benchland of broad valleys with a gentle gradient that accommodated large volumes of glacial meltwater. Extensive tracts are mapped in the Athabasca River valley from Jasper townsite to the Sunwapta River in Jasper. The AT1 Ecosite is the only AT Ecosite mapped in Banff. It is found in both the lower North Saskatchewan and lower Bow River valleys.

Geomorphology

The AT1 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B). Some tracts retain an irregular channeled (Eroded modifier, C.S.S.C. 1978b) surface as evidence of the braided streams that formed them. The AT1 areas have generally remained stable, accumulating a thin, discontinuous veneer of altered, medium textured eolian material (Eolian material B). This veneer occurs sporadically in Jasper and is more common to the south. A thin veneer of calcareous, medium textured eolian material (Eolian material A) occurs in the Athabasca River valley downstream from Jasper townsite and locally near the east gate in the North Saskatchewan River valley.

Recent fluvial material (slope wash) occasionally mantles portions of the terraces abutting steeper slopes that are gullied. Present watercourses often form one boundary of, or bisect AT1 tracts.

The AT1 tracts are often mapped as having complex slopes. Within tracts, slopes between 1 and 15% are most common. Treads of the terraces make up a majority of the area, and have linear, gentle slopes. These contrast with the short steeper risers or scarps between terrace levels.

Irregular surfaces are also typical of tracts that have inclusions of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). These inclusions are of two kinds. They may be integral parts of the landform such as the esker near the Cascade Road trailhead in Banff over which the Lake Minnewanka Road is built. Secondly, they may be knolls of ice contact material, remnants of a former landscape surface that are incompletely planed smooth or buried in the genesis of the AT landform, such as those found in the vicinity of the junction of the David Thompson highway with the Icefields Parkway in Banff.

Soils

Soils of AT1 are Orthic and Eluviated Eutric Brunisols. The latter occur most frequently in association with Eolian material B. These soils are genetically similar, with taxanomic separation being based on the depth of the surface eluvial (Ae) horizon. Table 104 describes a pedon sampled near Two Jack Lake in Banff that illustrates soils of AT1. Color Plate 2 is a photograph of this pedon.

Table 104 Pedon (Alberta 1977 No. 132) description of an Eluviated Eutric Brunisol of the AT1 Ecosite.

The variable depth (0-8 cm) of the Ae horizon indicates that this pedon falls on the taxonomic boundary between Orthic and Eluviated Eutric Brunisols. It has an eolian-glaciofluvial parent material disconformity in the solum. The lower portion of the B horizon has a low residual calcium carbonate content typical of soils of the Ecosite. The low extractable iron and aluminum values in the B horizon developed in the eolian material indicate a weak weathering environment. The gravelly coarse textures in the lower horizons are typical, though somewhat coarser than usual in the IICk3. Variable calcium carbonate content is depositional in the lower horizons.

Soils of AT1 are rapidly to well drained because of the pervious nature of the glaciofluvial materials and the low precipitation in the Montane. Seeps are very rare, occurring only occasionally at some landform breaks. Deep water tables are usually associated with AT1.

Turbic phases of AT1 soils occur sporadically throughout the landscape where windthrow of trees has disturbed the solum. Lithic phases are absent because of the thickness of the glaciofluvial material that usually also overlies other unconsolidated materials.

Vegetaton

The lodgepole pine/juniper/bearberry (C3), lodgepole pine/buffaloberry/showy aster (C6), and lodgepole pine/buffaloberry/twinflower (C19) v.t.s are dominant on AT1. The C3 v.t. is the most widely distributed, but any of these three may dominate a given tract. The C19 v.t. occurs most frequently close to the Lower Subalpine boundary, and C6 is dominant on all AT1 tracts in the North Saskatchewan River valley.

Most tracts of AT1 occur in accessible major valleys and have generally been influenced by fire within the past century. Thus, much of the AT1 vegetation is seral although some C3 stands appear to be mature. Table 105 describes a plot sampled at the same site as the pedon in Table 104 and illustrates the C3 v.t. on AT1. Plate 8 is a photograph of this plot area.

Though this plot is classified as an example of the C3 v.t., it has a lower cover of *Juniperus communis* and a higher cover of *calamagrostis rubescens* and *Elymus innovatus* than modal. The understory suggests elements of the Douglas fir/hairy wild rye (C1) v.t., an inclusion on AT1 tracts in isolated patches that have escaped intense fire for several hundred years. Some sites in side valleys of the lower Athabasca River valley in Jasper may have spruce forest.

Table 105 Stand (JD7114) illustrating the lodgepole pine / juniper / bearberry (C3) v.t. of the AT1 Ecosite.

Discussion

The AT1 Ecosite occurs on one of the most stable unconsolidated landforms in the parks. The valley floor position is remote from disturbance such as snow avalanching. The

AT1 Ecosite does not occur as a complex with Miscellaneous Landscapes. Tracts in the Athabasca River valley in the vicinity of Jasper Lake in Jasper, and towards the east gate in the North Sasktchewan River valley in Banff may have thin veneers of actively accumulating calcareous, medium textured eolian material (Eolian material A). Locally they may resemble Talbot 3 (TA3).

The dry condition of AT1 means that it is likely more susceptible to fire than other Ecosites. Tracts of AT1B show the effects of recent fire on vegetation in the North Saskatchewan River valley just above its confluence with the Howse River in Banff.

Tracts of AT1 are frequently disturbed by human activity, especially in the major accessible valleys. Borrow pits are common, usually along the transportation and utility corridors that traverse the gentler slopes of this Ecosite. The Jasper townsite and Whistlers campground are examples of development common on AT1 tracts.

Glaciofluvial terraces identical to AT1 may occur, but only locally, in tracts mapped as members of the Patricia (PT) Ecosection or Norquay 3 (NY3) Ecosite. The PT Ecosection concept is distinguished from the AT Ecosection concept by calcareous, medium textured till (Till C), while NY3 is distinguished by the calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). In the transition zone from Montane to Lower Subalpine, AT1 resembles and is mapped adjacent to its Lower Subalpine eqivalent, Bow Valley 1 (BV1). Fireside 1 (FR1) often adjoins and closely resembles AT1, but the former is found on calcareous, coarse, stratified fluvial material (Fluvial material B). The FR1 Ecosite often is mapped on fluvial fans that mantle the glaciofluvial material typical of the AT1 Ecosite, such as the fan of Johnston Creek in Banff. Vegetation differences that distinguish AT1 from AT3 are outlined in Table 103. In the Athabasca River valley below Jasper townsite, some AT1 tracts have patchy areas of junegrass-pasture sage-wild blue flax (H6), too small to be delineated as AT3.

AT3 - ATHABASCA 3 ECOSITE

Ecosite Concept

The AT3 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Montane Ecoregion. Orthic Eutric Brunisols are dominant soils, while a pattern of junegrass-pasture sage-wild blue flax (H6) with a lower percentage of lodgepole pine/juniper/bearberry (C3) is the prevalent vegetation.

The AT3 Ecosite is restricted to the Athabasca River valley floor and lower benchland in Jasper, between Jasper townsite and the Snake Indian River. It is the less extensive of the two AT Ecosites. The largest tract surrounds the Henry House area.

Geomorphology

The AT3 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B). Much of the glaciofluvial material in this area of the Athabasca River valley varies from modal Glaciofluvial material B in two ways. It is lower in lime because of the extensive are of noncalcareous bedrock in the Athabasca drainage above Jasper townsite. Secondly, the bedding structures present, with their variable texture and coarse fragment content, indicate a gentler stream gradient with a slower aggradation rate than modal. These conditions are usually found some distance removed from the melting ice front.

The AT3 areas have generally remained stable, but evidence suggests a thin vener of calcareous, medium textured eolian material (Eolian material A) has recently accumulated. The lower coarse fragment content results in deposits that are more easily eroded than the more gravelly materials of AT1. Along the lower margins of tracts mapped as AT3 erosional scarps frequently abut fluvial Ecosites.

Some areas retain an irregular channeled (eroded) surface as evidence of the braided streams that formed them. Locally, slopes can be complex, but treads of the terraces with gentle linear slopes are so dominant in areal extent, that tracts are mapped with simple slope type. Slopes are less that 5% except on the few short, steep scarps between terrace levels.

Soils

Current additions of calcareous, medium textured eolian material to the soils of AT3 result in an overblown phase (C.S.S.C. 1978b) of Orthic Eutric Brunisols. A varied geomorphic history on this Ecosite can be inferred from the distribution and genesis of these soils. Evidence suggests that at some time in the past, weakly developed Eutric Brunisols, similar to those presently found on AT1 in the absence of eolian veneer, were dominant soils on AT3 tracts. This genesis was brought to an end by the deposition of calcareous, medium textured eolian material (Eolian material A). Lime leached from this material has recalcified the buried B horizons. Constant eolian additions have produced Ahk rather than eluvial A (Ae) horizons.

An overblown phase of an Orthic Eutric Brunisol, sampled near Henry House, is presented in

Table 106 and represents soils of AT3. This pedon may also be classified as Orthic Melanic Brunisol.

The surface veneer of this pedon is lower in silt than is modal for Eolian material A, but another sample of this same veneer taken within 500 m was 81% silt. The infusion of secondry carbonate into the buried B horizons is well demonstrated by the calcium carbonate equivalent values, as is the accumulation of organic material in the Ahk horizon. The iron and aluminum data indicate any or all of 1) parent material low in primary minerals, 2) a short duration of weathering, or 3) a weak weathering environment. The summer temperature of this pedon is warmer than those of most other Eosites in the parks.

Soils of AT3 are rapidly drained because of the low precipitation in this area of the Athabasca River valley and the pervious nature of the glaciofluvial material. Deep water tables are associated with AT3.

Vegetation

The vegetation of AT3 is a pattern dominated by junegrass-pasture sage-wild blue flax (H6) with a lesser abundance of lodgepole pine/juniper/bearberry (C3). As all AT3 tracts occur in the Athabasca River valley in the drier area below Jasper townsite, fire has had a major effect on these tracts. The addition of calcareous, medium textured eolian material (Eolian material A) is also a factor contributing to the vegetation assemblage. Table 107 describes a plot of the H6 v.t. sampled at the same site as the pedon described in Table 106. Plate 72 shows this vegetation plot area. This plot has modal characteristics of the H6 v.t.

Table 107 Stand (IC5003) illustrating the junegrass-pasture sage-wild blue flax (H6) v.t. of the AT3 Ecosite.

Local areas on most stable positions may have the Douglas fir/hairy wild rye (C1) v.t., for instance, in the vicinity of Lake Edith. White spruce/juniper/bearberry (O17) occurs in local areas wher eolian material is more actively accumulating, such as close to the floodplain of the Athabasca River.

The pattern of grassland and forest vegetation is only weakly reflected in the soils. Soil morphology varied slightly between the vegetation settings, but soil classification remains constant. Eolian veneers, enriched in organic material (dark colored Ahk or ACk horizons), are thicker and more strongly expressed in areas of grassland, but also occur throughout the forested portions. Buried Brunisolic profiles occur throughout AT3 tracts, but horizons are most strongly expressed under the thinner eolian veneer of the forested areas.

Discussion

The history and future of AT3 tracts can be inferred from the combined evidence of geomorphology, soils and vegetation. Because of the infusion of carbonate, evident in the B horizon of the buried Brunisolic profiles, these Brunisols formed prior to the deposition of the eolian material. They probably developed under vegetation similar to forests on the present AT1 Ecosite, as the morphology and chemical characteristics are similar. Next, some agent or combination of agents, such as drier climatic conditions and fire, removed this forest for an extended period, leaving these areas open to an episode of eolian deposition. During this eolian accretion, grassland vegetation was probably dominant, with conditions similar to those presently found on the Talbot 2 (TA2) Ecosite. Soil morphology in the eolian veneer is similar, in both Ecosites, with grassland organic material accumulation in the surface horizons. Presently, on AT3 tracts, there is a tension between forest and grassland, with the former encroaching on the latter. The dry, warm conditions and eolian aggradation necessary for the maintenance of the junegrass-pasture sage-wild blue flax (H6) v.t. (cf TA2 Ecosite) are present, but not rigorous enough to check forest encroachment without the aid of concomitant fires. In the absence of fire and under present conditions, AT3 is expected to become identical to AT1 as it likely was in its earlier history. This evolution has occurred on forested portions of AT3, where eolian veneers and soils retain vestiges of grassland vegetation influence (dark colored Ahk or ACk horizons) despite being completely forested, except for small, local patches of grassland.

The AT3 Ecosite occurs on one of the most stable landforms in the parks. Except for the accumulation of a very thin veneer of eolian material, the level valley floor position is not subject to any geomorphic disturbance.

The AT3 does not occur as complexes with Miscellaneous Landscapes, or with Ecosite modifiers.

Because of their accessible location and gently sloping landform, most AT3 tracts are presently disturbed by transportation corridors. In the Henry House vicinity, the Canadian National Railway, the Yellowhead Highway and the Jasper airstrip all occupy part of the same AT3 tract. Of the other tracts, all but one have secondary roads traversing them.

Talbot 2 (TA2) differs from AT3 because the rate of eolian aggradation and depth of eolian material is greater than AT3. Also TA2 is found on steep southerly aspects. Hillsdale 4 (HD4) has similar eolian veneer, soils and vegetation but occurs on calcareous, coarse, stratified fluvial material (Fluvial material B). The vegetation pattern that separates AT3 from AT1 is outlined in Table 103.

AZ - AZURE ECOSECTION

The Azure Ecosection is found on noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) in the Upper Subalpine portion of the Subalpine Ecoregion. Complex slopes result in a dry-wet pattern of soils and vegetation. Dystric Brunisols and Engelmann spruce-subalpine fir open forest occupy upland positions, while poorer drainage in depressions produces Gleysolic and Organic soils with wet shrub thickets and wet herb meadows.

The AZ Ecosection is all but restricted to the Main Ranges where noncalcareous bedrock source areas, especially Gog Group quartzites, are extensive enough that little or no limestone is incorporated into the ice contact stratified material. The AZ Ecosection is quite limited in extent and distribution in Banff and southern Jasper. In northern Jasper, the headwaters of Blue Creek near Azure Lake and the Miette Pass vicinity contain the most extensive tracts. Only one AZ Ecosite (AZ1) is recogized (Table 108). Fig. 30 shows AZ distribution in a schematic landscape.

Table 108 General features of the Azure 1 (AZ1) Ecosite.

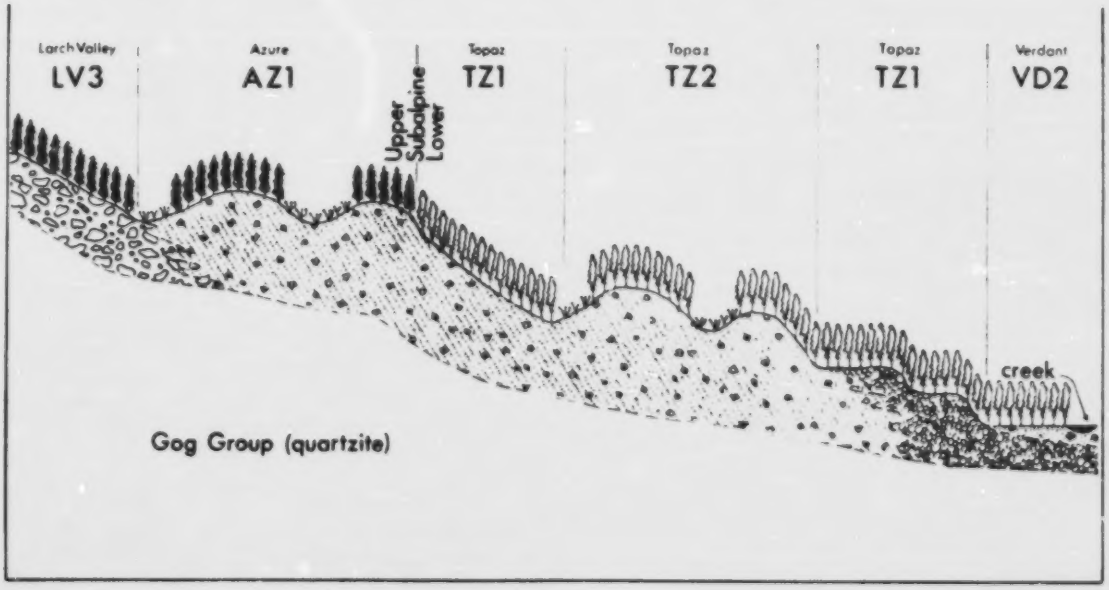
Figure 30 Landscape schematic showing the relationship of the Azure 1 (AZ1) and Topaz 1 (TZ1) Ecosites to other Ecosites.



AZ1 - AZURE 1 ECOSITE

Ecosite Concept

The AZ1 Ecosite is comprised of hummocky and ridged noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) in the Upper Subalpine portion of the Subalpine Ecoregion. This landform produces a dry-wet landscape pattern dominated by upland with Eluviated Dystric Brunisols and Engelmann spruce-subalpine fir/heather (O10). The poorly drained soils of depressions are Rego Gleysols more frequently than Terric Mesisols with willow/cinquefoil (S8) and mountain marigold-globeflower (H9) v.t.s.

The AZ1 Ecosite is a valley floor and lower slopes Ecosite of broad valleys with gentle grades along their length and surrounded by noncalcareous bedrock. These conditions are found, though infrequently, in the Main Ranges, often in association with Gog Group (quartzite) bedrock.

Geomorphology

Landforms of the AZ1 Ecosites are composed of noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) with hummocky and ridged surface expression. Slopes are usually complex and range from 5 to 45%. Glaciofluvial ice contact processes appear to have been dominant in the creation of these landforms, as indicated by coarse, stratified materials and features such as ice marginal channels and eskers. Dominant quartzite lithology also contributes to coarseness of textures.

Some of the depressional localities occupied by small, often intermittent, streams have been modified by the addition of fluvial veneers. Where water is ponded, small, shallow, horizontal fens have developed.

In the Miette Pass area in Jasper tracts of AZ1 have a discontinuous, noncalcareous, fine textured, glaciolacustrine veneer over the ice contact material.

Tracts of AZ1 in Banff have a thin surface veneer of altered, medium textured eolian material (Eolian material B).

Soils

A pattern of soils related to drainage, Plate 87, is produced by the complex slopes of the landform. Drier uplands make up approximately 70% of any tract and are dominated by rapidly to well drained Eluviated Dystric Brunisols. These soils show morphological evidence of comparatively strong development such as thick Ae horizons and strongly colored, thick B horizons. A pedon, sampled in upper Blue Creek, illustrative of the upland soils of AZ1, is described in Table 109 and shown in Color Plate 3.

The weak cementation (duric tendency) typical of coarse textured, noncalcareous soils in Banff and Jasper is present in the lower B horizon of this pedon.

The kind of soils found in wet (imperfectly to very poorly drained) depressions between ridges and hummocks depends on depth to the water table and landform modification. Rego Gleysols are the most common soils and are found with surface fluvial modification. These soils often have organic surface horizons that may be up to 40 cm thick and form a pattern in the depressions with the less frequently encountered Terric Mesisols on fens.

Other wet soils less frequently encountered in the depressions are Gleyed Dystric Brunisols found in wet positions where the glacial materials are not modified by fluvial or organic landform processes. These areas may have any or all of the genetically similar Gleyed Dystric Brunisols, Orthic Gleysols or gleyed Podzols, especially in Banff where altered, medium textured eolian material (Eolian material B) is present.

Vegetation

A pattern of vegetation types related to drainage variation caused by complex slopes and depth to water table is found on AZ1. Drier uplands, approximately 70% of any tract, are predominantly Engelmann spruce-subalpine fir/heather (O10) v.t.. A plot from upper Blue Creek < 1 km from the pedon described in Table 109 illustrates the O10 v.t. of AZ1 in Table 110.

Table 110 Stand (JE9043) illustrating the Engelmann spruce-subalpine fir / heather (O10) v.t. of dry upland segments of the AZ1 Ecosite.

This plot differs from modal O10 because of the high cover of both *Betula glandulosa* and lichens. These conditions, however, are typical of the O10 v.t. on AZ1. The variation especially the higher lichen cover, is attributable to more xeric and acidic surface conditions through rapid surface drainage on the coarse textured, noncalcareous material. Other v.t.s on upland portions of AZ1 include Engelmann spruce-subalpine fir/heather/feathermoss (C34) and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21). Engelmann spruce-subalpine fir/grouseberry (C15) is common on AZ1 in Banff and is the dominant v.t. of the tract near Haiduk Lake. Vegetation in the depressions on AZ1 depends strongly on the hydrologic conditions as influenced by the landform. Ridged landforms often have a wet, fluvial modified veneer in the lower positions, and willow/cinquefoil (S8) is more frequent than mountain marigold-globeflower (H9). Depressions in hummocky areas, or those with standing shallow water, are less common and may have H9, cottongrass/moss (H10), or water sedge-beaked sedge (H11), especially in association with organic soil and landform. Engelmann spruce-subalpine fir/valerian-fleabane (O9) occurs where open forest is established in wet portions of AZ1.

Discussion

Dry portions of the AZ1 Ecosite are quite simple and uniform taxonomically in landform, soil and vegetation. The subdominant, wet depressions are more complex, and except for their limited areal extent would be classified as Ecosites within either the Sphinx (SX) or Num-Ti-Jah (NT) Ecosections.

Upland positions may resemble closely the Larch Valley Ecosites LV2 and LV3 but these Ecosites are found on noncalcareous, coarse textured till (Till A). Topaz 2 (TZ2) has a similar dry-wet pattern and like AZ1 is found on noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A), but is a Lower Subalpine Ecosite. Both LV and TZ tracts are frequently mapped adjacent to AZ1 on the landscape.

Nigel 1 (NG1) is distinguished because it occurs on calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) and does not have a dry-wet pattern.

The AZ1 tract at Palliser Pass in extreme southern Banff is interpreted to occur in association with middle Paleozoic, quartz sandstone bedrock lithology rather than Gog Group quartzite. Vegetation on this tract has been significantly modified by fire.

BK - BAKER CREEK ECOSECTION

The Baker Creek (BK) Ecosection encompasses ridged and hummocky glacial landforms consisting of calcareous, medium textured till (Till C) or calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) throughout the Lower Subalpine portion of the Subalpine Ecoregion of Banff and Jasper. Its complex topography forms a compound landscape comprised of about 70% dry (well drained, mesic) upland segments and 30% wet (poorly to very poorly drained, hygric, to hydric) depressions between ridges and hummocks. Baker Creek (BK) Ecosites occur most often on the benchland of broad river valley floors, less often on the floors of narrower valleys and on lower valley wall slopes.

Upland segments are dominated by Eutric Brunisols that frequently exhibit luvisolic tendencies associated with weathering of calcareous glacial deposits under well drained, mesic conditions within the Lower Subalpine. Brunisolic Gray Luvisols are usually the subdominant soils. The dominant vegetation of upland segments, lodgepole pine or Engelmann spruce-subalpine fir forest, reflects complex fire histories. Pedogenically related Gleysolic and Organic soils occur on the wetland segments usually under wet spruce open forest, wet shrubby meadow, and/or birch fen. These depressional areas are often small closed basins in which seepage and surface waters accumulate. Shallow ponds often occur, especially on the BK1 and BK4 Ecosites. Some of the depressions have drainage outlets to nearby streams.

Genetic material differences and pine versus spruce dominated upland segments differentiate the three Baker Creek (BK) Ecosites as outlined in Table 111. Fig. 31 shows, schematically, the relative positions of the BK Ecosites and a few other Lower Subalpine Ecosites. Rarely do tracts of BK1, BK4 and BK6 adjoin as shown. Upland segments of BK1, BK4 and BK6 are similar to the Panorama Ridge 2 (PR2), Panorama Ridge 6 (PR6) and Bryant 2/Bryant 4 (BY2/BY4) Ecosites, respectively. Wetland segments resemble the Consolation Valley 1 (CV1), Hector 1 (HC1) and Hector 4 (HC4) Ecosites.

Table 111 General features of the Baker Creek (BK) Ecosites.

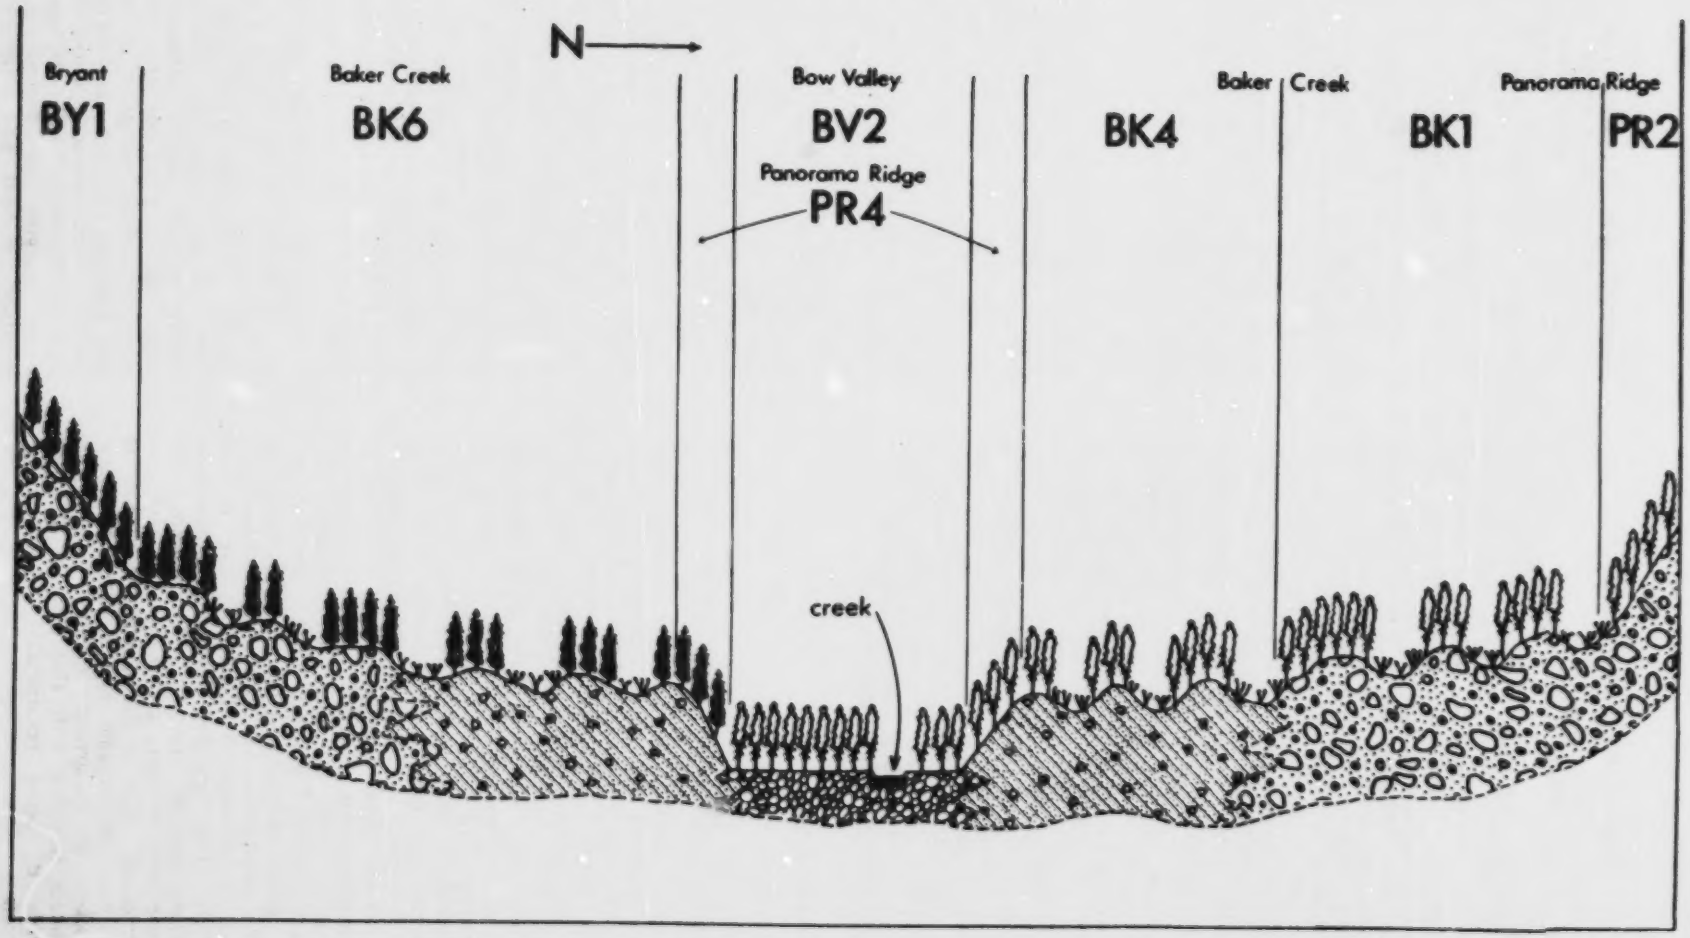
Figure 31 Landscape schematic showing relative positions of the Baker Creek (BK) Ecosites and a few other Lower Subalpine Ecosites.



BK1 - BAKER CREEK 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BK1, occurs on hummocky or ridged morainal landforms consisting of calcareous, medium textured till (Till C). Landform surface expression may be of depositional origin or controlled by underlying bedrock. Its complex topography forms a compound landscape comprised of about 70% dry (well drained, mesic) upland segments and 30% wet (poorly to very poorly drained, hygric to hydric) depressions between ridges and hummocks. Upland segments are characterized by a soil pattern in which Eluviated Eutric Brunisols are dominant, Orthic Eutric Brunisols and Brunisolic Gray Luvisols are subdominant. Luvisolic tendencies are common in the Brunisolic soils. Vegetation of upland segments is dominated by the lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s. Wet depressional segments contain pedogenically related wet soils best represented by the Rego Gleysol and Terric Mesisol Subgroups. Associated wet vegetation usually includes the spruce/Labrador tea/brown moss (O11), dwarf birch-shrubby cinquefoil-willow/brown moss (S1), and/or dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s, with S1 being most abundant.

Geomorphology

The BK1 Ecosite is typified by morainal landforms consisting of calcareous, medium textured till (Till C). Surficial veneers of altered, medium textured eolian material (Eolian material B) occur extensively on BK1 tracts located in western Banff and southwestern Jasper, sporadically elsewhere. Depressional segments are usually thinly mantled by peat derived primarily from sedges and brown mosses (eg. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally wood fragments may be found. Where the peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b) recognizing that in some localities, fen vegetation has been succeeded by open forest. The fen peat is underlain, within the control section, by till, occasionally by calcareous, coarse, stratified fluvial material (Fluvial material B) and altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) veneers. In some sites, volcanic ash material is well preserved in eolian or fluviolacustrine veneers at or near the organic layer's lower boundary. Pockets of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) occur occasionally in some BK1 tracts.

Topographically, the BK1 Ecosite displays a series of subparallel or parallel ridges or irregularly distributed knolls (hummocks) separated by gently sloping depressions. Slopes commonly range from 5 to 30% although a few BK1 tracts with slopes ranging to 45% occur. Depressional segments, usually with slopes <5%, are generally concave and bowl shaped with subtle margins. The ridged and hummocky surface expressions may reflect underlying bedrock surfaces or be of depositional origin. Fluted ground moraine is an outstanding example of depositional ridged moraine (e.g. Bow River valley near Baker Creek, Plate 84). BK1 tracts on failed till slopes occur infrequently. Morainal veneers occur locally on some ridge and hummock crests but dominate on the few BK1X tracts mapped. Bedrock outcrops are not common except on BK1+R tracts.

Soils

Soils of the BK1 Ecosite are distributed in a pattern governed by drainage conditions. Soils of the well drained, upland segments are distributed in a pattern reflecting the thickness of the eluvial (Ae) horizon and the degree of luvisolic development. Eluviated Eutric Brunisols are dominant, Orthic Eutric Brunisols and Brunisolic Gray Luvisols subdominant. These soils have weak textural B horizons, some with sufficient pedogenic clay film development to be Bt horizons, occurring at or slightly below the till surface. Iron, aluminum and humus enriched Bm horizons developed in the altered, medium textured eolian (Eolian material B) veneers may occur above the textural B horizons. Orthic Gray Luvisols occur in minor amounts. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly expressed in the absence of altered, medium textured eolian material. In some localities, surface erosion inhibits Ae development. Lithic soils are common only on BK1X tracts. Gleyed Eutric Brunisols, Gleyed Eluviated Eutric Brunisols, Gleyed Brunisolic Gray Luvisols and Gleyed Gray Luvisols often occur in narrow transitional belts surrounding wet depressions. A pedon illustrating Brunisolic Gray Luvisols of upland segments of the BK1 Ecosite is described in Table 112 and shown on Color Plate 4.

A variety of pedogenically related soils occur on the poorly to very poorly drained, depressional segments of the BK1 Ecosite. These are best represented by the Rego Gleysol and Terric Mesisol Subgroups. Mineral layers are usually strongly gleyed reflecting high water tables and long periods of saturation; conditions that inhibit pedogenic horizonation. Orthic Gleysols are important accessory soils in localities with shorter periods of saturation such as depressions with drainage outlets and along margins of depressions. Favorable moisture, nutrient and vegetation conditions

have resulted in the accumulation of varying thicknesses of fen peat on the depressional soils. Terric Mesisols occur where the peat is >40 cm thick. Other Organic soils with subdominant humic or fibric layers, gleyed Podzols, gleyed Regosols and Humic Gleysols occur occasionally. A pedon illustrating Rego Gleysols of wet depressional segments of the BK1 Ecosite is described in Table 113.

Vegetation

Vegetation of the BK1 Ecosite is distributed in a pattern governed by drainage conditions. The closely related lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s dominate the well drained, mesic upland segments and reflect the extensive effects of fire in the Lower Subalpine. Lodgepole pine/buffaloberry/showy aster (C6) at low elevations and lodgepole pine/false azalea/grouseberry (C20) in western regions of the parks are important

accessory v.t.s. Lodgepole pine/juniper/bearberry (C3), including a variant with high spruce cover occurring in eastern Banff, lodgepole pine/green alder/feathermoss (C10), lodgepole pine/feathermoss (C11) and lodgepole pine/Labrador tea (C29) occur in minor amounts. Modification of the vegetation by recent fires has occurred in some areas. A stand representing vegetation of the pedon sampling site described above (Table 112) and illustrating the C18 v.t. of upland segments of the BK1 Ecosite is presented in Table 114 and Plate 88.

but some depressions are dominated by O11 or S3. Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6), Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) and water sedge-beaked sedge (H11) occur in minor amounts. A stand representing vegetation of the pedon sampling site described above (Table 113) and illustrating the *O11 v.t. of wet depressions of the* BK1 Ecosite is described in Table 115.

Discussion

The BK1 Ecosite encompasses a compound landscape pattern consisting of well drained upland segments similar to the Panorama Ridge 2 (PR2) Ecosite and poorly to very poorly drained depressional segments similar to the Consolation Valley 1 (CV1) Ecosite and occasionally, the Hector 1 (HC1) and Hector 4 (HC4) Ecosites. The proportion of wet depressions on BK1 tracts commonly ranges from 20 to 40%. Map presentation of BK1 tracts at scales larger than 1:50,000 is invalid because these segments would become mappable as separate Ecosites. The BK1 Ecosite is separated from BK4 by genetic material differences, and from BK6 by genetic material and vegetation differences as outlined in Table 111. The Patricia 5 (PT5) Ecosite is the Montane counterpart of BK1.

BK4 - BAKER CREEK 4 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BK4, occurs on hummocky or ridged, moraine-like, glacial landforms consisting of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Landform surface expression may be of depositional origin or controlled by underlying bedrock. Its complex topography forms a compound landscape comprised of about 70% dry (well drained, mesic) upland segments and 30% wet (poorly to very poorly drained, hygric to hydric) depressions between ridges and hummocks. Upland segments are characterized by a soil pattern in which Eluviated Eutric Brunisols are dominant; Orthic Eutric Brunisols and Brunisolic Gray Luvisols are subdominant. Luvisolic tendencies are common in the Brunisolic soils. Vegetation of upland segments is dominated by the lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s. Wet depressional segments contain pedogenically related wet soils, best represented by the Rego Gleysol and Terric Mesisol Subgroups. Associated wet vegetation usually includes the spruce/Labrador tea/brown moss (O11), dwarf birch-shrubby cinquefoil-willow/brown moss (S1), and/or dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s, with S1 being most abundant.

Geomorphology

The BK4 Ecosite is typified by moraine-like glacial landforms consisting of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). A low lime phase occurs occasionally. Tracts of BK4 in the vicinity of Topaz 1 (TZ1) or Topaz 2 (TZ2) tracts occur on ice contact stratified material with low lime content and coarse textures (e.g. Athabasca River valley below the Chaba River confluence). Surficial veneers of altered, medium textured eolian material (Eolian material B) occur extensively on BK4 tracts located in western Banff and southwestern Jasper, sporadically elsewhere. Depressional segments are usually thinly mantled by peat derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally, wood fragments may be found. Where this peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b), recognizing that in some localities, fen vegetation has been succeeded by open forest. The fen peat is underlain, within the control section, by till, occasionally by calcareous, coarse, stratified fluvial material (Fluvial material B) and altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) veneers. In some sites, volcanic ash is well preserved in eolian or fluviolacustrine veneers at or near the organic layer's lower boundary.

Topographically, the BK4 Ecosite displays a series of parallel ridges or irregularly distributed knolls separated by gently sloping depressions. Slopes commonly range from 5 to 30%, although a few BK4 tracts with slopes ranging to 45% occur. Depressional segments, usually with slopes <5%, may be level with sharp borders to upland segments or concave and bowl shaped with subtle margins. The ridged and hummocky surface expressions may reflect underlying bedrock surfaces or be of depositional origin. Kettle-holes, kames and eskers are outstanding depositional features that occur on some BK4 tracts. Small glaciofluvial terraces occur occasionally. Veneers of ice contact stratified material occur locally on some ridge and hummock crests but dominate on the few BK4X tracts mapped. Bedrock outcrops are not common except on BK4+R tracts.

Soils

Soils of the BK4 Ecosite are distributed in a pattern governed by drainage conditions. Soils of the well drained, upland segments are distributed in a pattern reflecting the thickness of the eluvial (Ae) horizon and degree of luvisolic development. Eluviated Eutric Brunisols are dominant, Orthic Eutric

Brunisols and Brunisolic Gray Luvisols subdominant. These soils have weak textural B horizons, some with sufficient pedogenic clay film development to be Bt horizons, occurring at or slightly below the glacial material surface. Iron, aluminum, and humus enriched Bm horizons developed in the altered, medium textured eolian (Eolian material B) veneers may overlie the textural B horizons. Orthic Gray Luvisols occur in minor amounts. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly expressed in the absence of altered, medium textured eolian material. In some localities surface erosion inhibits Ae development. Lithic soils are common only on BK4X tracts. Gleyed Eutric Brunisols, Gleyed Eluviated Eutric Brunisols, Gleyed Brunisolic Gray Luvisols and Gleyed Gray Luvisols often occur in narrow transitional belts surrounding wet depressions. A pedon illustrating Eluviated Eutric Brunisols of upland segments of the BK4 Ecosite is described in Table 116 and shown in Color Plate 5. The sampling site is shown in Plate 89.

A variety of pedogenically related soils occur on the poor to very poorly drained, depressional segments of the BK4 Ecosite. These are best represented by the Rego Gleysol and Terric Mesisol Subgroups. Mineral layers are usually strongly gleyed reflecting high water tables and long periods of saturation; conditions that inhibit pedogenic horizonation. Orthic Gleysols are important accessory soils in localities with shorter periods of saturation such as depressions with drainage outlets and raised margins of depressions. Favorable moisture, nutrient, and vegetation conditions have resulted in the accumulation of varying thicknesses of fen peat on the depressional soils. Terric Mesisols occur where the peat is >40cm thick. Other Organic soils with subdominant humic or fibric layers, gleyed Podzols, gleyed Regosols and Humic Gleysols occur occasionally. The pedon described in Table 113 for wet depressions of the BK1 Ecosite illustrates Rego Gleysols occurring on the BK4 Ecosite.

Vegetation

Vegetation of the BK4 Ecosite is distributed in a pattern governed by drainage conditions. The closely related lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s dominate the well drained, mesic upland segments and reflect the extensive effects of fire in the Lower Subalpine. Lodgepole pine/juniper/bearberry (C3), lodgepole pine/buffaloberry/showy aster (C6), lodgepole pine/false azalea/grouseberry (C20) and lodgepole pine/Labrador tea (C29) are commonly occurring accessory v.t.s. The C3 v.t. is common on subxeric to mesic, well to rapidly drained, exposed sites such as prominent ridge and hummock crests. On some tracts near Banff's eastern boundary, a C3 variant with significant amounts of spruce is quite common. The C6 is closely related to the dominant v.t.s and occurs with them at low elevations. The C20 v.t. occurs primarily in the Main Ranges; C29 is most abundant in eastern Jasper. Lodgepole pine/feathermoss (C11) occurs in minor amounts. Modification by recent fires has occurred in some localities. A stand illustrating the C19 v.t. of upland segments of the BK4 Ecosite is described in Table 117. This stand is located about 1 km up valley from the pedon sample site described in Table 116.

Discussion

The BK4 Ecosite encompasses a compound landscape pattern consisting of well drained upland segments similar to the Panorama Ridge 6 (PR6) Ecosite and poorly to very poorly drained depressional segments similar to the Consolation Valley 1 (CV1) Ecosite, occasionally the Hector 1 (HC1) and Hector 4 (HC4) Ecosites. The proportion of wet depressions on BK4 tracts commonly ranges from 20 to 40%. Map presentation of BK4 tracts at scales larger than 1:50,000 is invalid because these segments would become mappable as separate Ecosites. BK4 is separated from BK1 by genetic material differences, from BK6 by vegetation differences as outlined in Table 111. In areas where the Patricia 5 (PT5) Ecosite occurs on calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B), it is the Montane counterpart of BK4.

BK6 - BAKER CREEK 6 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BK6, occurs on hummocky or ridged glacial landforms consisting of calcareous, medium textured till (Till C) and calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Landform surface expression may be of depositional origin or controlled by underlying bedrock. Its complex topography forms a compound landscape comprised of about 70% dry (well drained, mesic) upland segments and 30% wet (poorly to very poorly drained, hygric to hydric) depressions between ridges and hummocks. Upland segments are characterized by a soil pattern in which Eluviated Eutric Brunisols are dominant, Orthic Eutric Brunisols subdominant. Vegetation of upland segments is dominated by the Engelmann spruce-subalpine fir/feathermoss (C13) v.t. Wet depressional segments contain pedogenically related wet soils, best represented by the Orthic Gleysol, Rego Gleysol and Terric Mesisol Subgroups. Vegetation of depressions is dominated by the spruce/Labrador tea/brown moss (O11), dwarf birch-shrubby cinquefoil-willow/brown moss (S1) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s.

The BK6 Ecosite occurs more often on narrow valley bottom and headwall areas than does BK1 and BK4. Because of this slightly different physiographic position, BK6 exhibits a slightly different drainage pattern in which many depressions have drainage outlets whereas the BK1 and BK4 depressions are predominantly closed basins. This difference is reflected in the kind of soil that occurs in the wet depressions.

Geomorphology

The BK6 Ecosite is typified by glacial landforms consisting of calcareous, medium textured till (Till C) and calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). A low lime phase occurs occasionally. Surficial veneers of altered, medium textured eolian material (Eolian material B) occur extensively on BK6 tracts located in western Banff and southwestern Jasper and sporadically elsewhere. Depressional segments are usually thinly mantled by peat derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally, wood fragments may be found. Where this peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b) recognizing that in some localities fen vegetation has been succeeded by open forest. The fen peat is underlain, within the control

section, by till, occasionally by calcareous, coarse, stratified fluvial (Fluvial material B) veneers, infrequently by altered, fine, stratified fluviolacustrine (Fluviolacustrine material A) veneers. The BK6 Ecosite has more open ended depressional basins than BK1 and BK4, consequently, fluvial veneers tend to be more abundant on BK6. In some sites, volcanic ash material is well preserved in eolian or fluviolacustrine veneers at or near the organic layer's lower boundary.

Topographically, the BK6 Ecosite displays a series of subparallel ridges or irregularly distributed knolls separated by gently sloping depressions. Slopes commonly range from 5 to 45%. Depressional segments, usually with slopes <5%, may be level with sharp borders to upland segments or concave and bowl shaped with subtle margins. The ridged and hummocky surface expressions may reflect underlying bedrock surfaces or be of depositional origin. Tracts of BK6 occasionally include failed till slopes. Small glaciofluvial terraces occur occasionally. Veneers of till or ice contact stratified material occur locally on some ridge and hummock crests and dominate on the few BK6X tracts mapped. Bedrock outcrops are not common except on BK6+R tracts.

Soils

Soils of the BK6 Ecosite are distributed in a pattern governed by drainage conditions. Soils of the well drained upland segments are distributed in a pattern reflecting the degree of eluvial (Ae) horizon development. Eluviated Eutric Brunisols are dominant, Orthic Eutric Brunisols subdominant. These soils have B horizons that range from the weak textural horizons frequently associated with weathering of calcareous glacial material to the comparatively advanced Bm and Bf horizons associated with altered, medium textured eolian material (Eolian material B). Orthic and Brunisolic Gray Luvisols and Orthic Humo-Ferric Podzols occur in minor amounts. Soils with luvisolic tendencies are especially evident on the drier slopes of eastern Banff and Jasper. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly expressed in the absence of altered, medium textured eolian material. In some localities surface erosion inhibits Ae development. Lithic soils are common only on BK4X tracts. Gleyed Eutric Brunisols and Gleyed Eluviated Eutric Brunisols often occur in narrow transitional belts surrounding wet depressions. The pedons described in Tables 137 and 138 for the Bryant 2 (BY2) and Bryant 4 (BY4) Ecosites illustrate Orthic Eutric Brunisols of upland segments of the BK6 Ecosite.

A variety of pedogenically related soils occurs on the poorly to very poorly drained, depressional segments of the BK6 Ecosite. These are best represented by the Orthic Gleysol, Rego Gleysol and Terric Mesisol Subgroups. Mineral layers are usually strongly gleyed reflecting high water tables and long periods of saturation; conditions that inhibit pedogenic horizonation. Recent and continuing fluvial activity in some localities inhibits pedogenic horizonation and organic material accumulation. Orthic Gleysols occur in localities with shorter periods of saturation such as depressions with drainage outlets and raised margins of depressions. Favorable moisture, nutrient and vegetation conditions have resulted in the accumulation of varying thicknesses of fen peat on most depressional soils. Terric Mesisols occur where the peat is >40 cm thick. Other Organic soils with subdominant humic or fibric layers, gleyed Podzols, gleyed Regosols and Humic Gleysols occur occasionally. The pedon described in Table 113 for wet depressions of the BK1 Ecosite illustrates Rego Gleysols occurring on the BK6 Ecosite.

Vegetation

Vegetation of the BK6 Ecosite is distributed in a pattern governed by drainage conditions. The Engelmann spruce-subalpine fir/feathermoss (C13) v.t. dominates the well drained upland segments. Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) are important accessory v.t.s. The C14 v.t. is common on relatively steep slopes in the Main Ranges, and C30 and C31 are more abundant in eastern Banff and Jasper, with C31 occurring mainly on southerly aspects. Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) occurs occasionally near the Continental Divide and in northern Jasper. Fire affected vegetation, in which spruce rather than pine is regenerating, occurs in some areas, e.g. upper Bryant Creek valley in Banff.

Vegetation of depressional segments, dominated by the spruce/Labrador tea/brown moss (O11), dwarf birch-shrubby cinquefoil-willow/brown moss (S1) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s. reflects poor drainage. Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6), Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14), willow/cinquefoil (S8) and water sedge-beaked sedge (H11) occur in minor amounts. A stand illustrating the S1 v.t. of wet depressional segments of the BK6 Ecosite is described in Table 119.

Discussion

The BK6 Ecosite encompasses a compound landscape pattern consisting of well drained upland segments similar to the Bryant 2 (BY2) or Bryant 4 (BY4) Ecosites and poorly to very poorly drained depressional seg-

ments similar to the Consolation Valley 1 (CV1), Hector 1 (HC1) or Hector 4 (HC4) Ecosites. The proportion of wet depressions on BK6 commonly ranges from 20 to 40%. Map presentation of BK6 tracts at scales larger than 1:50,000 is invalid because these wet and dry segments would become mappable as separate Ecosites. The BK6 Ecosite is separated from BK1 and BK4 by vegetation differences as outlined in Table 111. In terms of physiographic position, landform surface expression and vegetation cover, BK6 resembles the Cavell 1 (CA1) Ecosite. However, CA1 occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B) and is dominated by acidic soils (Dystric Brunisols). The Peyto Lake 5 (PL5) Ecosite is the Upper Subalpine counterpart of BK6.

BP - BOULDER PASS ECOSECTION

The Boulder Pass (BP) Ecosection encompasses stabilized, hummocky landslide (colluvial) deposits that are variably textured and derived from either calcareous or noncalcareous bedrock. It is dominated by Brunisolic and Regosolic soils associated with mixed coniferous open forest, Engelmann spruce-subalpine fir open and closed forests, and subalpine larch-subalpine fir forest. The BP Ecosection occurs on most physiographic positions in the Upper Subalpine portion of the Subalpine Ecoregion in both parks.

Two Boulder Pass Ecosites are differentiated primarily on vegetational differences as outlined in Table 120. Fig. 32 shows physiographic positions of BP1 and BP2 Ecosites in relation to adjacent Ecosites.

BP1 - BOULDER PASS 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, BP1, encompasses stabilized, hummocky landslide (colluvial) deposits that are variably textured and derived from either calcareous or noncalcareous bedrock. The BP1 Ecosite is dominated by rapidly to well drained Orthic Eutric Brunisols, Orthic Dystric Brunisols, and Orthic Regosols associated with the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) v.t.

Geomorphology

The BP1 Ecosite encompasses stabilized, hummocky landslide (colluvial) deposits. Extinct rock glaciers are occasionally included. These postglacial deposits usually overlie morainal or bedrock surfaces. They range from medium acid to extremely calcareous in reaction and, texturally, from silt loam to loamy sand. The deposits have a high proportion of variably sized angular and subangular coarse fragments. Tracts of BP1 often have a high proportion of the surface occupied by stones and boulders. Surface expression is hummocky with a wide range of slopes, most often

Table 120 General features of the Boulder Pass (BP) Ecosites.

Ecosite	Landform	Soils	Vegetation
BP1	Landslide material; hummocky	Brunisolic, Regosolic	mixed coniferous open forest
BP2	Landslide material; hummocky	Brunisolic	Engelmann spruce-subalpine fir open and closed forests, subalpine larch-subalpine fir forest

between 15 and 70%. Tracts of BP1 occurring on valley walls display hummocky depositional surfaces superimposed upon inclined slopes that reflect the underlying bedrock or morainal surfaces. Surrounding tracts often include failed till slopes. Landslide scars often occur above and adjacent to tracts of BP1.

Soils

The BP1 Ecosite is dominated by rapidly to well drained Orthic Eutric Brunisols, Orthic Dystric Brunisols, and Orthic Regosols. These soils develop on landslide deposits that reflect the nature of the bedrock from which they have been derived. Orthic Eutric Brunisols develop on the more abundant calcareous slides and Eluviated Dystric Brunisols develop on the noncalcareous materials. Orthic Regosols occur more often on the calcareous bedrock-derived slides. Soils are absent on portions of tracts that have large amounts of stones and boulders on the surface (tracts mapped as BP1+CL). The soils on BP1 are often fragmental at depth. Small areas of Eluviated Eutric Brunisols and Eluviated Dystric Brunisols occur where discontinuous surficial veneers of altered, medium textured eolian material (Eolian material B) are present and are usually associated with patches of closed forest. Also, small areas of Orthic Melanic Brunisols and Orthic Sombric Brunisols occur on steep slopes that are subject to soil creep. A pedon described in Table 121 and shown in Color Plate 6 illustrates an Orthic Eutric Brunisol on BP1.

Vegetation

The BP1 Ecosite is dominated by the subxeric Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) v.t. This kind of vegetation is common on BP1 and appears to be related to the high amount of stones and boulders and the lack of fine earth material, a combination which makes tree establishment and growth difficult. Mountain avens-snow willow-moss campion (H1) and Engelmann spruce-subalpine fir/mountain avens (O1^{0}) are accessory v.t.s that occur on exposed slopes near the Upper Subalpine-Alpine boundary. Sparsely vegetated, very rubbly patches occur with O4 on tracts mapped as BP1+CL. Patches of the Engelmann spruce-subalpine fir/grouseberry (C15), subalpine larch-subalpine fir/grouseberry-everlasting (C23), and Engelmann spruce-subalpine fir/heather (O10) v.t.s usually indicate where more fine earth occurs and soils are better developed. A stand illustrating the O4 v.t. is described in Table 122 and shown in Plate 91 and represents the vegetation at the pedon sample site described above in Table 121. This plot contains more heather cover than is usual for the O4 v.t.

Discussion

Vegetation differences separate BP1 from BP2 as outlined in Table 120. Portions of BP1 most resemble the Miscellaneous Landscape

CL (Colluvial Landslide). The latter is differentiated by the absence of soil and by less than 20% vegetation cover. The BP1 Ecosite is the Upper Subalpine counterpart of the Ishbell 2 (IB2) Ecosite.

BP2 - BOULDER PASS 2 ECOSITE

Ecosite Concept

The Boulder Pass 2 (BP2) Ecosite encompasses stabilized, hummocky landslide (colluvial) deposits that are variably textured and derived from either calcareous or noncalcareous bedrock. The BP2 is dominated by well to moderately well drained Orthic and Eluviated Eutric Brunisols associated with the Engelmann spruce-subalpine fir/grouseberry (C15), subalpine larch-subalpine fir/grouseberry-everlasting (C23), and Engelmann spruce-subalpine fir/heather (O10) v.t.s.

Geomorphology

The BP2 Ecosite encompasses stabilized, hummocky landslide (colluvial) deposits. Extinct rock glaciers are occasionally included. These postglacial deposits usually overlie morainal or bedrock surfaces. They range from medium acid to extremely calcareous in reaction and, texturally, from silt loam to loamy sand. The deposits have a high proportion of variably sized angular and subangular fragments. Tracts of BP2 have a low proportion of the surface occupied by stones and boulders compared to BP1. Surficial veneers of altered, medium textured eolian material (Eolian material B) occur extensively in western Banff and southwestern Jasper, sporadically elsewhere. Surface expression is irregular with a wide range of slopes, most often between 15 and 70%. The BP2 tracts occurring on valley walls display hummocky depositional surfaces superimposed upon inclined slopes that reflect the underlying bedrock or morainal surfaces. Surrounding tracts often include failed till slopes. Landslide scars often occur above and adjacent to tracts of BP2.

Soils

The BP2 Ecosite is dominated by well to moderately well drained Orthic and Eluviated Eutric Brunisols. These soils develop on calcareous landslide deposits that reflect the nature of the bedrock from which they have been derived. Orthic and Eluviated Dystric Brunisols occur in minor amounts on less frequently occurring noncalcareous landslide deposits. Soils associated with BP2 have better developed horizons than do BP1 soils. This is attributed to generally older, more weathered surfaces and the concomitant extensiveness of altered, medium textured eolian (Eolian material B) veneers in some areas. Podzolic soils occur in small amounts where Eolian material B is present. A pedon described in Table 123 and shown in Color Plate 7 illustrates an Eluviated Eutric Brunisol on BP2. This pedon was sampled at Boulder Pass below the southwest end of Ptarmigan Lake in Banff.

Vegetation

The BP2 Ecosite is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/heather (O10), and subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t.s. The C23 v.t. is the least extensive but dominates several BP2 tracts in southern Banff south of Hector Lake, Pipestone Pass, and the Panther River. Small amounts of the Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t. mainly occur on noncalcareous slides. Patches of open forest v.t.s and nonvegetated areas (CL) occur on portions of the landscape that have a high proportion of the surface occupied by stones and boulders. A vegetation plot description of the C23 v.t. is illustrated in Table 124 and shown in Plate 92 and represents the vegetation of the sampled pedon described in Table 123.

Discussion

The BP2 Ecosite is separated from the BP1 Ecosite primarily on vegetational differences as outlined in Table 120. Copper 1 (CP1) Ecosite, when it occurs on failed slopes, resembles BP2. However, CP1 occurs on landforms consisting of noncalcareous, medium textured residuum (Residuum A) and is dominated by lithic phase Dystric Brunisols containing shaly or slaty coarse fragments that conform in orientation to the bedding planes in the underlying parent rock. The BP2 Ecosite is the Upper Subalpine counterpart of the Ishbell 3 (IB3) Ecosite.

BS - BOW SUMMIT ECOSECTION

The Bow Summit (BS) Ecosection encompasses steep, usually linear, colluvial landforms comprised of calcareous, medium textured colluvium (Colluvium C) in the Alpine Ecoregion of Banff and Jasper. It occurs on or below steep, rocky walls in areas that are geologically dominated by calcareous strata.

Eutric and Melanic Brunisols, Regosols, and Humic Regosols characterize the soil component of BS. These well drained soils reflect the calcareous, medium textured parent material. The vegetation component is characterized by mountain avens tundra. Only one Ecosite (BS1) is recognized within the BS Ecosection. Its general features are outlined in Table 125. Figs. 51 and 53, show schematically the physiographic position of BS1 on the landscape in relation to other Ecosites.

BS1 - BOW SUMMIT 1 ECOSITE

Ecosite Concept

The Alpine Ecosite, BS1, occurs on blankets and veneers consisting of calcareous, medium textured colluvium (Colluvium C) overlying bedrock on steep valley walls. The soil component is dominated by Orthic Eutric Brunisols, Orthic Melanic Brunisols, Orthic Regosols, and Orthic Humic Regosols. The vegetation component is dominated by the mountain avens-snow willow-moss campion (H1) v.t.

Geomorphology

The BS1 Ecosite occurs on blankets and veneers consisting of calcareous, medium textured colluvium (Colluvium C) overlying inclined bedrock on steep valley walls. Underlying bedrock is predominantly calcareous strata. Colluviation, including soil creep and avalanching, occurs locally. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically and are most abundant on BS1 tracts of western Banff and southwestern Jasper. Erosional and colluvial processes have obliterated most

Table 125 General features of the Bow Summit (BS1) Ecosite.

Ecosite	Landform	Soils	Vegetation
BS1	Colluvium C; blanket, veneer	Eutric Brunisol, Melanic Brunisol, Regosol, Humic Regosol	mountain avens tundra

of the evidence of these eolian veneers. Rubble, without fine earth material for soil development, is common on some BS1 tracts, particularly those occurring below steep rock walls. Solifluction and cryoturbation are common modifying features of BS1.

Topographically, BS1 displays long, linear, inclined slopes commonly ranging from 45 to 100%. Tracts of BS1 with complex topography have linear slopes whose continuity is broken by one or more steep bedrock escarpments. Surface form is controlled by deposition and underlying bedrock. The colluvial material is usually shallowest (veneers) at the tops of slopes and deepens downslope. Colluvial veneers dominate BS1X tracts and bedrock exposures dominate tracts mapped as BS1+R.

Soils

Soil development and distribution on the BS1 Ecosite is affected by the degree of colluvia-

tion and humus incorporation at the surface and, to a lesser degree, by avalanching. Orthic Eutric Brunisols, Orthic Melanic Brunisols, Orthic Regosols, and Orthic Humic Regosols are the dominant soils. Orthic Eutric Brunisols occupy localities where Ah horizon development is weak and eluvial (Ae) horizon development is inhibited or destroyed. Orthic Melanic Brunisols and Orthic Humic Regosols occupy localities where humus accumulation in the upper sola is evident. Locally, colluviation has physically thickened surface organo-mineral horizons. Orthic Regosols occur where geomorphic activity is frequent and intense, such as sparsely vegetated rubbly sites.

Soils mapped in the BS1 Ecosite are well drained and their profile development reflect the influence of the calcareous, medium textured parent material. The Brunisolic soils have thin sola and weakly developed Bm or Bmk horizons. Orthic Melanic Brunisols and Orthic Humic Regosols have thick Ah horizons. Orthic Eutric Brunisols and Orthic Regosols may have thin Ah horizons. Cumulic Regosols and Cumulic Humic Regosols occur in minor amounts. Turbic soil phases occur occasionally on BS1 tracts. Lithic soil phases dominate tracts mapped as BS1X. A pedon illustrating Orthic Melanic Brunisols of BS1 is dscribed in Table 126 and shown in Color Plate 8. This pedon was sampled on a north slope above Sunwapta Pass on the Jasper side of the Banff-Jasper boundary. The upper solum of this pedon is developed in a mixture of Eolian material B and Colluvium C.

Vegetation

Distribution of vegetation on BS1 reflects the degree of colluvial activity, exposure, and elevation. The mountain avens-snow willow-moss campion (H1) v.t. is dominant. Mountain avens-kobresia-bearberry (H4) and heather-everlasting (L5) are accessory v.t.s. Small amounts of the white mountain heather-mountain avens-snow willow (L4) v.t. occur in late snow lie areas. Other v.t.s. in small amounts are saxicolous lichen (H12) and hairy wild rye-junegrass-bearberry (H14). Unvegetated portions asociated with rubbly colluvium and Regosolic soils on intensely active sites constitute up to 50% of tracts mapped as BS1, or up to 80% of BS1+T or BS1+CR tracts. A plot illustrating the mountain avens-snow willow-moss campion (H1) v.t. on BS1 is described in Table 127. Plate 93 shows the landscape and vegetation of BS1.

Discussion

In terms of landform surface expression, physiographic position, and vegetation cover, BS1 resembles the Redoubt 1 (RD1) and Tekarra 1 (TK1) Ecosites. However, RD1 occurs on colluvial landforms consisting of noncalcareous, medium textured colluvium (Colluvium B), TK1 occurs on noncalcareous, coarse textured colluvium (Colluvium A) rather than the calcareous colluvium associated with BS1. Also RD1 and TK1 differ because they have acidic soils. The Wildflower (WF) Ecosites are the Upper Subalpine counterparts to BS1.

BV - BOW VALLEY ECOSECTION

The Bow Valley (BV) Ecosection occurs on calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Lower Subalpine portion of the Subalpine Ecoregion. Soils characterizing BV are Eutric Brunisols; the vegetation is either lodgepole pine or Engelmann spruce-subalpine fir forest.

The BV Ecosection is found most frequently and with greatest extent on the broadest valley floors throughout the Lower Subalpine in Banff and Jasper. Extensive areas are mapped in the Bow River valley between Johnston Creek and Village Lake Louise in Banff and in the Athabasca River valley in the Sunwapta and Chaba confluence area in Jasper.

Three Ecosites (BV1, BV2, BV3) are recognized mainly on differences in vegetation. Table 128 shows general features of the BV Ecosection. A representation of BV Ecosites on the landscape is presented in Fig. 33.

Landform genesis of the BV Ecosection can be compared to the presently actively aggrading glaciofluvial landform of the Pipestone 4 (PP4) Ecosite.

Figure 33 Landscape schematic showing the relationships of the Bow Valley (BV) Ecosites to other Ecosites.

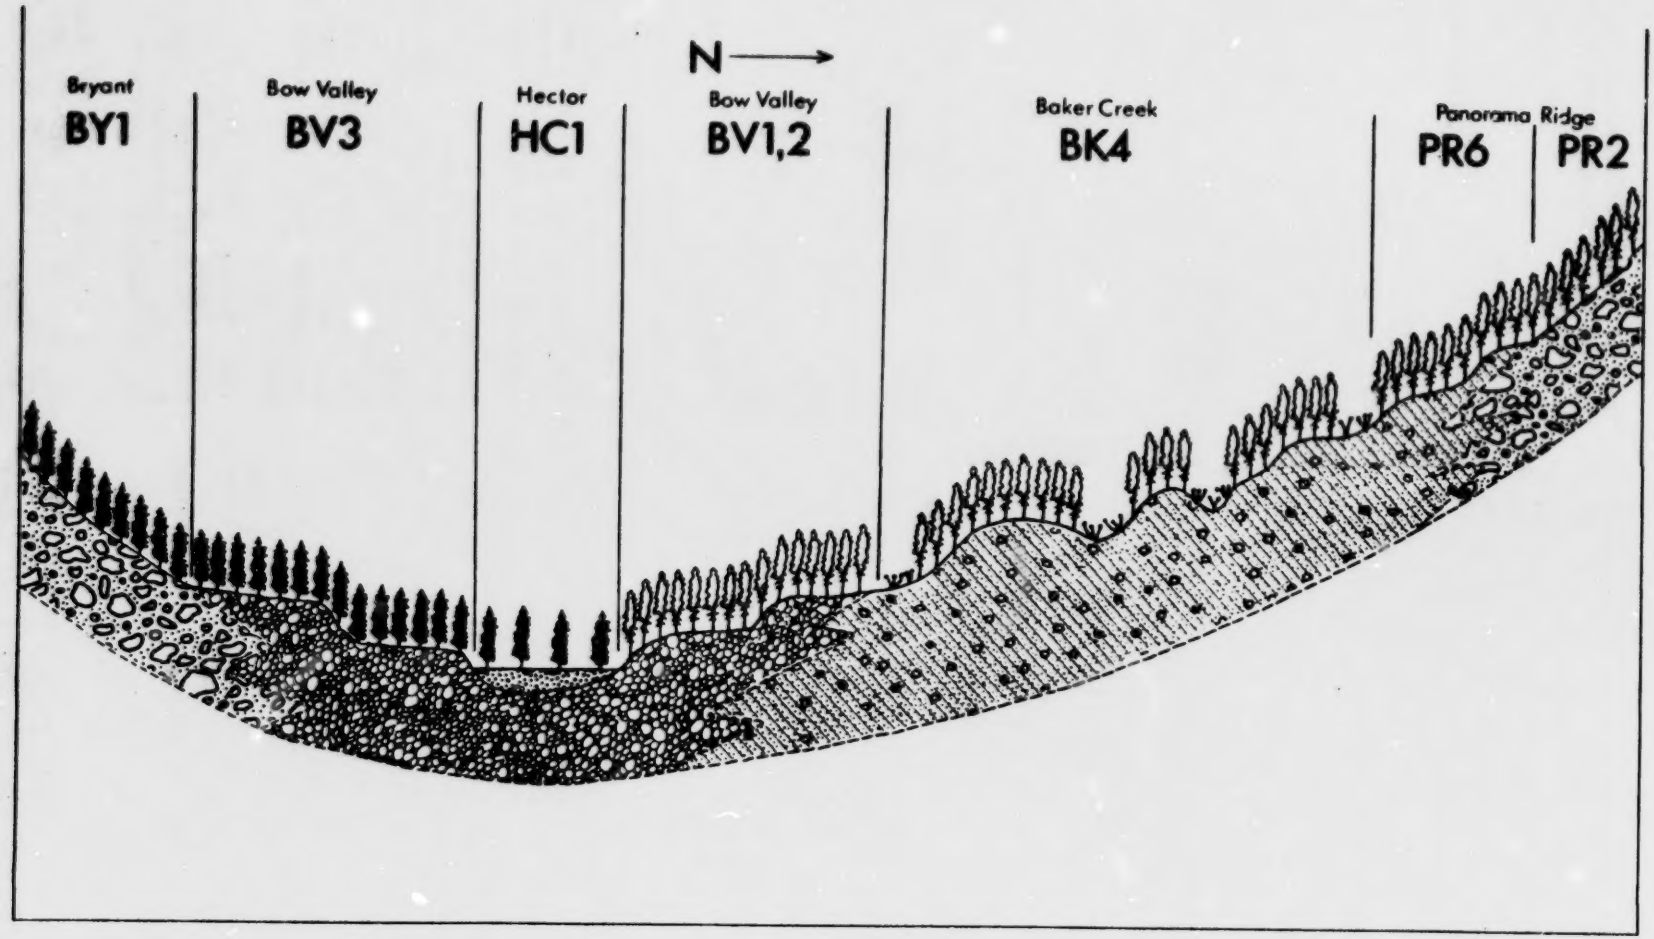

Table 128 General features of the Bow Valley (BV) Ecosites.

BV3	Glaciofluvial B; terrace	Eutric Brunisol	Engelmann spruce-subalpine fir forest

BV1 - BOW VALLEY 1 ECOSITE

Ecosite Concept

The BV1 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Lower Subalpine portion of the Subalpine Ecoregion. Orthic and Eluviated Eutric Brunisols are the dominant soils with lodgepole pine/dwarf bilberry (C9), lodgepole pine/buffaloberry/grouseberry (C18), and lodgepole pine/buffaloberry/twinflower (C19) as the major v.t.s. The BV1 Ecosite is the most extensive one of the BV Ecosection.

The BV1 Ecosite is found on floors and lower benchlands of broad valleys with gentle grades that once accommodated large volumes of glacial meltwater. Extensive tracts are mapped in the Bow River valley in Banff between Johnston Creek and Village Lake Louise, and adjacent to the Athabasca-Sunwapta confluence in Jasper.

Geomorphology

The BV1 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B). Some tracts retain an irregular channeled surface (Eroded modifier, C.S.S.C. 1978b) as evidence of the braided streams that formed them during deglaciation. These areas have generally remained stable, usually accumulating a thin mantle of altered, medium textured eolian material (Eolian material B), especially in western Banff and southwestern Jasper. Material (slope wash) occasionally mantles portions of terraces abutting steeper gullied slopes.

Other modifications of the landform, since original deposition, have occasionally been produced by recent fluvial processes. Some modern streams have incised into the glaciofluvial material, bisecting the original landform. Others, emerging from steeper land, have fanned out spreading a mantle of recent fluvial material. The Bow River and its tributaries have effected these changes at several locations between Village Lake Louise and Johnston Creek in Banff.

Overall, tracts are mapped as having complex slopes. Within tracts, slopes between 1 and 15% are most common. Treads of the terraces make up the majority of the area and have gentle linear slopes. These contrast with the short steeper scarps between terrace levels. Some tracts have small amounts of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) with hummocky surface form. This material is more variable in texture and coarse fragment content than the usually massively bedded glaciofluvial material. Complex slopes also exist in the infrequent instances where aggradation occurred in an area of hummocky bedrock. Incomplete burial has left isolated bedrock knolls in some BV1 tracts in the vicinity of Village Lake Louise.

Soils

Long-term landform stability and consistent parent materials have resulted in uniform soil development on BV1. Soils are Orthic and Eluviated Eutric Brunisols. The taxonomic separation is based on the depth of the surface eluvial (Ae) horizon in these otherwise similar soils. Table 129 describes an Eluviated Eutric Brunisol sampled in the Athabasca River valley in Jasper that illustrates soils of BV1. The variable depth (0-5 cm) of the Ae horizon indicates that this pedon falls on the taxonomic boundary between Orthic and Eluviated Eutric Brunisols. It has an eolian-glaciofluvial parent material disconformity in the solum and a residual calcium carbonate content in the lower B horizon below this disconformity that is typical of soils of the Ecosite. However, the usual luvisolic tendency (increase in clay) of this B horizon is not well demonstrated here. The low extractable iron and aluminum values for the upper B horizons which have developed in the eolian material, indicate a weak weathering environment.

Soils of BV1 are rapidly to well drained because of the pervious nature of the glaciofluvial material. Local seeps may affect both soils and vegetation at the margin of a tract where slopes break from steeper, adjoining, valley wall Ecosites. Terrace surfaces are generally high relative to the water table.

Turbic phases of BV1 soils occur sporadically throughout the landscape where windthrow from trees has disturbed the solum. This is most prevalent in tracts where materials have low coarse fragment content, such as on the BV1 tract adjacent to Kidney Lake in the Snake Indian River valley in Jasper. Lithic phases are absent because of the thickness of the glaciofluvial material that usually also overlies other unconsolidated materials.

Vegetation

The similar v.t.s, lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/buffaloberry/twinflower (C19), are dominant on BV1. The lodgepole pine/dwarf bilberry (C9) v.t. also occurs on BV1 in Banff, notable in the Eisenhower Junction vicinity in the Bow River valley. Lodgepole pine/juniper/bearberry (C3) is found on drier tracts in eastern Banff and Jasper where there is lower precipitation. Many BV1 tracts have been burned within the past century. Table 130 describes a plot sampled in the vicinity of the pedon in Table 129 and illustrates the C19 v.t. found on BV1. Plate 94 is a photograph of this plot area.

Discussion

The BV1 Ecosite occurs on one of the most stable unconsolidated landforms in the parks. The valley floor position is remote from disturbances such as snow avalanching. The BV1 Ecosite does not occur complexed with Miscellaneous Landscapes; however, an extensive area of BV1 is mapped as burned in the lower Chaba River valley in Jasper.

In accessible areas, BV1 tracts are often disturbed by human activity. Borrow pits are common, especially along the transportation and utility corridors that traverse the gentler slopes of this Ecosite. At Village Lake Louise, the campground and much of the village itself are developed on BV1 tracts.

Local glaciofluvial terraces in tracts mapped as Panorama Ridge 6 (PR6) or Baker Creek 4 (BK4) may be identical to BV1. However, both of the former Ecosites are found on calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) rather than glaciofluvial landforms. Where BV1 is mapped adjacent to and in the Montane—Subalpine transition zone, it is very similar to its Montane counterpart, Athabasca 1 (AT1), but the latter has lodgepole pine forests more typical of the Montane. The Upper Subalpine counterpart, Nigel 1 (NG1), is distinguished by its Engelmann spruce-subalpine fir forest. Vegetation differences that distinguish BV1 from BV2 and BV3 are outlined in Table 128.

BV2 - BOW VALLEY 2 ECOSITE

Ecosite Concept

The BV2 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Lower Subalpine portion of the Subalpine Ecoregion. Eluviated Eutric Brunisols dominate the Ecosite, but some tracts may be primarily Orthic Eutric Brunisols. Lodgepole pine/false azalea/grouseberry (C20) and lodgepole pine/Labrador tea (C29) are the predominant v.t.s.

BV2 is found on floors and lower benchland of broad valleys with gentle grades that accommodated large volumes of glacial meltwater. Extensive tracts are mapped between Village Lake Louise and Kicking Horse Pass in Banff, and adjacent to the Rocky River confluence with the creek draining Jacques Lake in Jasper.

Geomorphology

The BV2 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B). Some tracts retain an irregular channeled surface (eroded) as

evidence of the braided streams that formed them during deglaciation. These areas have generally remained stable, usually accumulating a thin mantle of altered, medium textured eolian material (Eolian material B), especially in western Banff.

Other landform modifications, since original deposition, have occasionally been produced by recent fluvial processes. Material (slope wash) occasionally mantles portions of terraces abutting steeper slopes that are gullied. Some modern streams have incised into the glaciofluvial material, bisecting the original landform. The stream draining Jacques Lake has bisected the BV2 on the Rocky River in Jasper.

Overall, tracts are usually mapped as having complex slopes. Within tracts, slopes between 1 and 15% are most common. Treads of the terraces have linear, gentle slopes and make up a majority of the area. These contrast with the short steeper scarps between terrace levels. Some tracts have small amounts of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) with hummocky surface form. This material is more variable in texture and coarse fragment content than the usually massively bedded glaciofluvial material. Complex slopes also exist in the infrequent instances where aggradation occurred in an area of hummocky bedrock. Incomplete burial has left isolated bedrock knolls in some BV2 tracts in the vicinity of Kicking Horse Pass in Banff.

Soils

Long-term landform stability and consistent parent materials have resulted in uniform soil development on BV2. Soils are Eluviated Eutric Brunisols and Orthic Eutric Brunisols, the former dominant on most tracts. These soils are similar but separated taxonomically on thickness of the surface eluvial (Ae) horizon. Table 131 describes a pedon sampled in lower Bath Creek valley in Banff that illustrates soils of BV2. Color Plate 9 shows this pedon.

The variable depth (0-3 cm) of the Ae horizon indicates that this pedon falls on the boundary between Orthic and Eluviated Eutric Brunisols. It has an eolian-glaciofluvial parent material disconformity in the solum with the typical residual calcium carbonate and clay content increase in the upper layer of the second material. This pedon has an anomolously high clay content in the Ae horizon. The low extractable iron and aluminum values for the B horizon, developed in the eolian material, indicate a weak weathering environment.

Soils of BV1 are well drained because of the pervious nature of the glaciofluvial material. Local seeps may affect both soils and vegetation at the margin of a tract where slopes break from steeper, adjoining, valley wall Ecosites. Terraced surfaces are generally elevated relative to the water table.

Turbic phases of BV2 soils occur sporadically throughout the landscape where windthrow of trees has disturbed the solum. Lithic phases are absent because of the thickness of the glaciofluvial material that also generally overlies other unconsolidated materials.

Vegetation

The lodgepole pine/false azalea/grouseberry (C20) and lodgepole pine/Labrador tea (C29) v.t.s are dominant on BV2. The C20 v.t. is most extensive on BV2 tracts in the western portion of the parks, while C29 dominates eastern tracts. The lodgepole pine/feathermoss (C11) is an accessory v.t. also found on BV2. Table 132 describes a plot sampled at the same site as the pedon in Table 131 and illustrates the C20 v.t. found on BV2.

The v.t.s on BV2 resemble and are seral to the successionally mature Engelmann spruce-subalpine fir v.t.s (C13, C14, C30) that occur on the BV3 Ecosite. These mature v.t.s may be found locally on BV2 in places that have escaped fire in the past few centuries.

Discussion

The BV2 Ecosite occurs on one of the most stable unconsolidated landforms in the parks. The valley floor position is generally remote from disturbances such as snow avalanching. In Banff, one BV2 tract on a bench in Bath Creek valley below Mount Bosworth is avalanched. No tracts are mapped as burned. Vegetation in its earliest successional stages following fire is mapped as BV1B on this landform in the Lower Subalpine. BV2 does not occur as a complex with Miscellaneous Landscapes.

In accessible areas, BV2 tracts are often disturbed by human activity. Borrow pits are common, especially along the transportation and utility corridors that traverse the gentler slopes of this Ecosite, for instance, near Kicking Horse Pass in Banff.

Local glaciofluvial terraces in tracts of Panorama Ridge 6 (PR6) or Baker Creek 4 (BK4) may be identical to BV2. However, both of the former Ecosites are found on calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Athabasca 1 (AT1) in the Montane, is similar to BV2, but occurs at lower elevations

with lodgepole pine forests more typical of the Montane. The Upper Subalpine counterpart, Nigel 1 (NG1), has an Engelmann spruce-subalpine fir forest. Vegetation differences that distinguish BV2 from BV1 and BV3 are outlined in Table 128.

BV3 - BOW VALLEY 3 ECOSITE

Ecosite Concept

The BV3 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Lower Subalpine portion of the Subalpine Ecoregion. Orthic and Eluviated Eutric Brunisols are the dominant soils, with Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) the dominant v.t.s. It is the least extensive BV Ecosite.

The BV3 Ecosite is found on floors and lower benchland of broad valleys with gentle grades that accomodated large volumes of glacial meltwater. This Ecosite is not extensive in any one area, but occurs sporadically throughout both parks in remote or sheltered areas that have escaped fire for the past several hundred years.

Geomorphology

The BV3 Ecosite occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B). Some tracts retain an irregular channeled surface (eroded) as evidence of the braided streams that formed them during deglaciation. These areas have generally remained stable, usually accumulating a thin mantle of altered, medium textured eolian material (Eolian material B), especially in western Banff and southwestern Jasper.

Recent fluvial material (slope wash) occasionally mantles portions of the terraces abutting steeper slopes that are gullied. Present watercourses often bisect or form one boundary of BV3 tracts.

Overall, tracts are usually mapped as having complex slopes. Within tracts, slopes between 1 and 15% are most common. Treads of the terraces make up a majority of the area, and have linear gentle slopes. These contrast with the short steeper scarps between terrace levels. Some tracts have small amounts of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) with hummocky surface form.

Soils

Long-term landform stability and consistent parent materials have resulted in uniform soil development. Soils are both Eluviated Eutric Brunisols and Orthic Eutric Brunisols with the former dominant on most tracts. These soils are similar but separated taxonomically on the thickness of the surface eluvial (Ae) horizon.

The pedon description contained in the BV2 description, Table 131, serves to illustrate soils of the BV3 Ecosite. A similar pedogenic environment is assumed for both of these Ecosites.

Soils of BV3 are well drained because of the pervious nature of the glaciofluvial material. Local seeps may affect both soils and vegetation at the margin of a tract where slopes break from steeper, adjoining, valley wall Ecosites. Terraced surfaces are generally elevated relative to the water table.

Turbic phases of BV3 soils occur sporadically throughout the landscape where windthrow of trees has disturbed the solum. Lithic phases are absent because of the thickness of the glaciofluvial material that also generally overlies other uncondolidated materials.

Vegetation

The successionally mature forests on BV3 reflect the stability of this Ecosite. Tracts are dominated by Engelmann spruce-subalpine fir/feathermoss (C13) close to the Continental Divide and by Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) to the east. Table 133 describes a plot, sampled in the Chaba River valley in Jasper near Fortress Lake, that illustrates vegetation of the BV3 Ecosite.

This plot and its setting illustrate well the stability of BV3. The Chaba River valley recently experienced an extensive burn. Perhaps fortuitously, but more probably because it is isolated from other forest stands, this tract escaped the nearby burn. This plot also illustrates that C13 on BV3 tracts close to the Continental Divide often contains elements of the Engelmann spruce-subalpine fir/false azalea (C14) v.t.

The C13 v.t. also grades to the similar Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t. from west to east. For instance, C31 is found on BV3 tracts in the Red Deer River valley in Banff.

Discussion

The BV3 Ecosite occurs on one of the most stable unconsolidated landforms in the parks. The valley floor position is generally remote from disturbances such as snow avalanching. Though not necessarily the rule, some BV3 tracts also are found in positions less subject to fire than tracts of other BV Ecosites with all other factors equal. Probably because of

a positive correlation between man's presence and fire, BV3 is not found in any readily accessible areas. The BV3 Ecosite does not occur as a complex with Miscellaneous Landscapes.

Local glaciofluvial terraces in tracts of Bryant 4 (BY4) or Baker Creek 6 (BK6) may be identical to BV3. However, both of these Ecosites are found on calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). The Montane counterpart of BV3, Athabasca 1 (AT1), is distinguished because is has lodgepole pine forest v.t.s. Nigel 1 (NG1), the Upper Subalpine counterpart of BV3, is very similar but is forested with Engelmann spruce-subalpine fir forest v.t.s typical of the Upper Subalpine. Vegetation differences that distinguish BV3 from BV1 and BV2 are outlined in Table 128.

BY - BRYANT ECOSECTION

The Bryant Ecosection is one of the most extensive in Banff and Jasper and encompasses glacial landforms comprised of calcareous, medium textured till (Till C) or calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) throughout the Lower Subalpine portion of the Subalpine Ecoregion. It occurs primarily on valley walls, shoulders and floors, including benchlands on broad valley floors, and is associated with calcareous bedrock strata.

The dominant soils, Eutric Brunisols, are moderately developed and reflect the calcareous, medium to variably textured parent materials and cool, moist, climax, Engelmann spruce-subalpine fir forests that dominate the vegetation component of the landscape. There are three Bryant Ecosites. As outlined in Table 134, different vegetation groups distinguish BY1 from BY2 whereas BY4 is separated from the first two by geomorphic material differences. Fig. 34 shows the relative positions of the Bryant Ecosites. Only occasionally does this combination dominate a valley as shown in the diagram. The Peyto Lake Ecosection is the Upper Subalpine counterpart of Bryant.

Table 134 General features of the Bryant (BY) Ecosites.

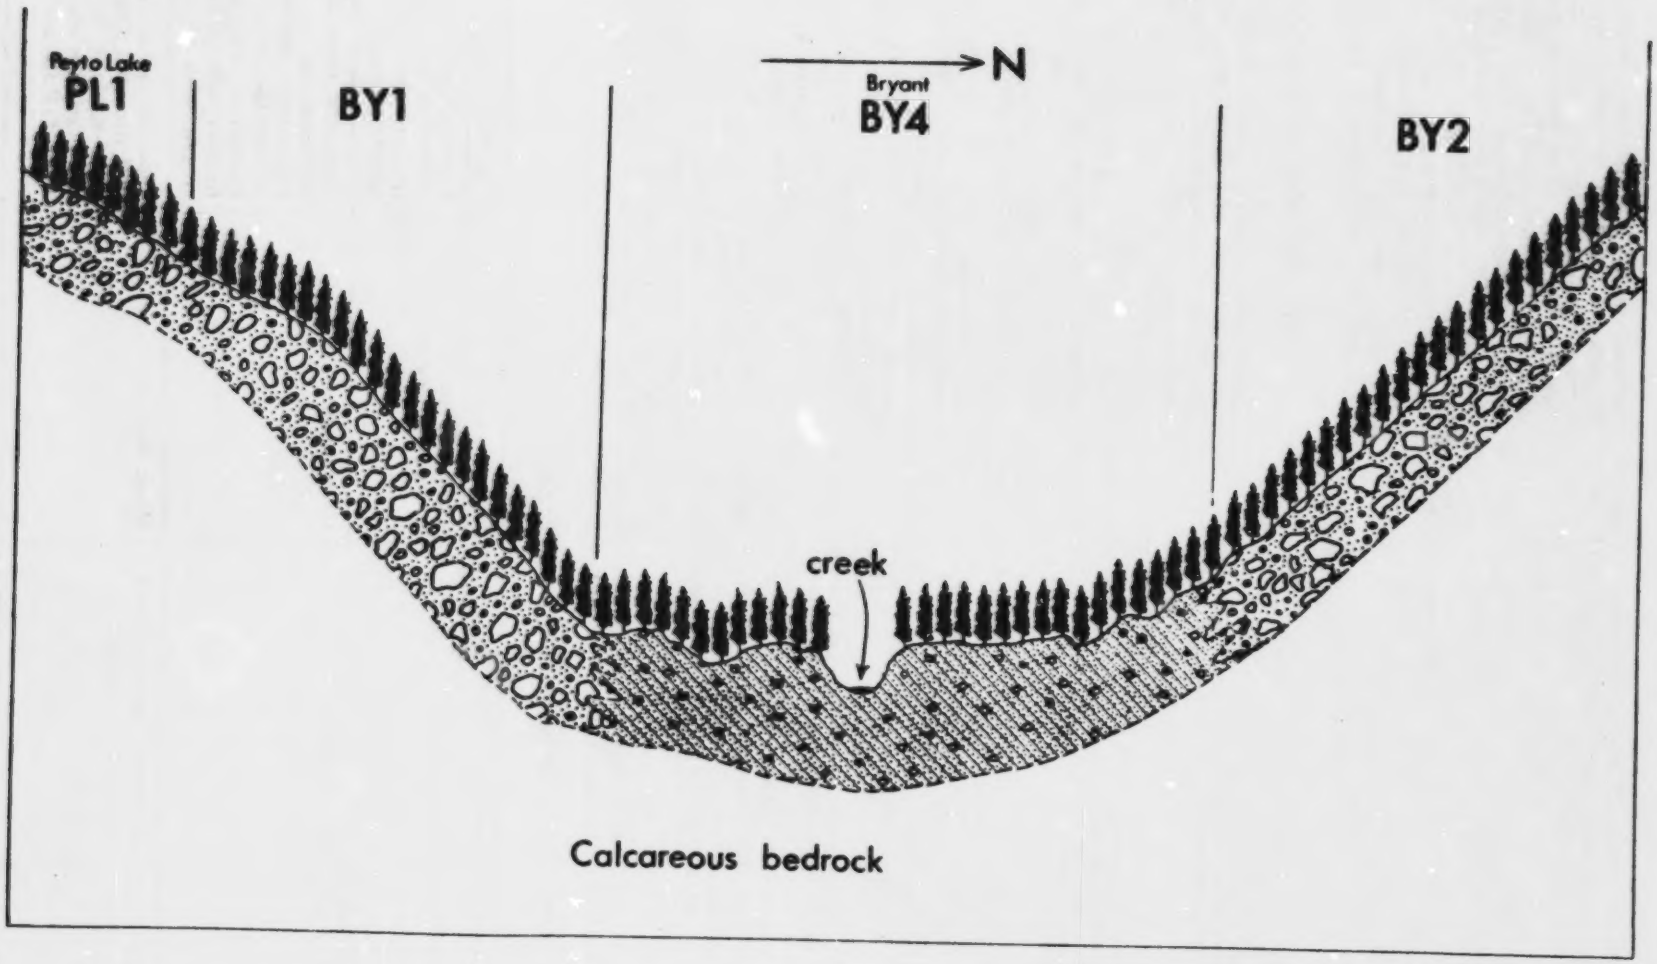
Figure 34 Landscape schematic showing the relationship of the Bryant (BY) Ecosites to other Ecosites.



BY1 - BRYANT 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite BY1, occurs on morainal blankets consisting of calcareous, medium textured till (Till C) overlying inclined bedrock on valley walls. Veneers of altered, medium textured eolian material (Eolian material B) occur extensively, and significantly influence soil development. Consequently BY1 exhibits a soil pattern in which Eluviated Eutric Brunisols are dominant, Orthic Eutric Brunisols and Orthic Humo-Ferric Podzols subdominant. Vegetation cover is dominated by the Engelmann spruce-subalpine fir/false azalea (C14) and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. The C14 v.t. is usually most abundant but some BY1 tracts are dominated by C21.

The BY1 Ecosite is usually found on northerly aspects in two distinct areas of the western Banff and Jasper. The western Banff - southwestern Jasper area corresponds to the extensive distribution of Eolian material B. The northwestern Jasper area, north of the range of *Vaccinium scoparium*, has significant amounts of the C21 v.t. The BY1 Ecosite is especially common in the Icefields area of Banff and Jasper where the calcareous glacial materials are derived from the carbonate-dominated upper Main Ranges stratigraphic column. Little BY1 is found in west-central Jasper because of extensive non-calcareous Lower Cambrian and Precambrian strata. The BY1 Ecosite occurs sporadically in eastern portions of Banff and Jasper.

Geomorphology

The BY1 Ecosite is typified by morainal blankets consisting of calcareous, medium textured till (Till C) overlying inclined bedrock on valley walls. Surface veneers of altered, medium textured eolian material (Eolian material B) are extensively distributed over BY1 tracts of western Banff and southwestern Jasper, sporadically distributed elsewhere. Colluvium derived from till and/or fractured bedrock is found occasionally on the steepest portions of the landscape. Calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) occurs occasionally.

Topographically, the BY1 Ecosite displays long linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes are normally 15 to 70% and are often dissected by subparallel gullies oriented perpendicular to the contour. Small fluvial fans and aprons emanating from gully mouths along valley bottoms or other major slope breaks may be included in BY1 tracts. Tracts of BY1 situated at valley confluences, on valley shoulders, on failed slopes, and occasionally along valley floors often display morainal landforms with irregular (5-45% complex slopes) topography. These landforms include morainal blankets and veneers overlying ridged and hummocky bedrock and the relatively deep till of hummocky moraines. Morainal veneers, also occasionally found on inclined slopes, dominate on BY1X tracts. Bedrock outcrops occur occasionally on all types of terrain and are relatively common on BY1+R tracts. Patches of colluvium forming blankets and veneers occur occasionally on the steepest terrain, particularly below bedrock escarpments.

Soils

Eluviated Eutric Brunisols are the dominant soils of the BY1 Ecosite. Orthic Eutric Brunisols and Orthic Humo-Ferric Podzols are subdominant. These three groups are intimately associated on the predominantly well to moderately well drained terrain and reflect, in their development, the Eolian material B veneers overlying calcareous till. They usually have relatively well developed Bm, Bf, or podzolic Bf horizons above the parent material disconformity. Immediately below are found relatively weakly expressed Bm or Btj horizons that sometimes exhibit a clay increase. This development is accompanied by a pronounced pH increase from the upper to lower solum. Across some portions of the landscape Ae horizons are weakly expressed or have been destroyed by recent surface modification processes such as avalanching, gullying, windthrow of trees, or shallow surface colluviation. Soils with Bhf and podzolic Bhf horizons occur occasionally. Some gullies and depressional localities contain seeps where wet soils are found. Orthic and Cumulic Regosols occur on steep, colluviating portions of the landscape. Lithic soil phases are not common except on BY1X tracts where they dominate. A pedon illustrating Eluviated Eutric Brunisols of the BY1 Ecosite is described in Table 135 and shown in Color Plate 10.

Vegetation

The BY1 Ecosite is dominated by the Engelmann spruce-subalpine fir/false azalea (C14) and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. Overall, C14 is more abundant but some BY1 tracts, particularly those located in northern Jasper and along the Continental Divide, are dominated by C21. The accessory v.t., Engelmann spruce-subalpine fir/feathermoss (C13), is often found near valley bottoms on more gently sloping lower slopes below C14 or C21 dominated valley walls. If large enough, these valley bottom localities are mapped as BY2.

Wet v.t.s such as Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) are

Discussion

The BY1 Ecosite is the most extensive Bryant Ecosite of the Main Ranges although BY2 and BY4 may be associated in some areas on valley floors and southerly aspects. The BY1 distribution roughly corresponds to the predominant distribution of Eolian material B and the C14 and C21 v.t.s.

Rather specific vegetation differences differentiate BY1 from BY2; landform and genetic materials differentiate BY1 from BY4 (Table 134). The Moraine Lake 1 (ML1) and Cavell 2 (CA2) Ecosites resemble BY1 in terms of topographic distribution, landform surface expression, and vegetation cover. The ML1 Ecosite is differentiated because it occurs on morainal landforms consisting of noncalcareous, coarse textured till (Till A), and CA2 because it occurs on noncalcareous, medium textured till (Till B). Both ML1 and CA2 are dominated by Dystric Brunisols. The ML1 soils have significantly thicker sola.

BY2 - BRYANT 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BY2, occurs on morainal blankets consisting of calcareous, medium textured till (Till C) overlying inclined bedrock on valley walls. Orthic and Eluviated Eutric Brunisols are the dominant soils. Vegetation cover is dominated by the Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30), and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.s. The C13 v.t. is most abundant but some BY2 tracts are dominated by C30 or C31.

The BY2 Ecosite is usually found in the Front Ranges of Banff and Jasper. Some areas of the Main Ranges have tracts of BY2 on valley floors and southerly aspects.

Geomorphology

The BY2 Ecosite is typified by morainal blankets of calcareous, medium textured till (Till C) overlying inclined bedrock on valley walls. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically. Colluvium consisting of till and/or fractured bedrock is found occasionally on the steepest portions of the landscape. Calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) occurs occasionally.

Topographically, the BY2 Ecosite displays long linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes are normally 15 to 70%. These slopes are often dissected by subparallel narrow ravines oriented perpendicular to the contour. Small fluvial fans and aprons emanating from gully mouths along the valley bottoms or other major slope breaks may be included in BY2 tracts. Tracts of BY2 situated along valley floors, on valley shoulders, at valley confluences, and on failed slopes often display morainal landforms with irregular (5 - 45%

complex slopes) topography. These landforms include morainal blankets and veneers overlying ridged and hummocky bedrock and the relatively deep till of hummocky moraines. Morainal veneers, also occasionally found on inclined slopes, are dominant on tracts mapped as BY2X. Bedrock outcrops occur occasionally on all types of terrain and are relatively common on BY2+R tracts.

Soils

The soils of the BY2 Ecosite are dominated by Orthic and Eluviated Eutric Brunisols. These well drained soils have B horizons that range from the rudimentary textural horizons frequently associated with weathering of calcareous till to the comparatively advanced Bm and Bf horizons associated with local occurrences of altered, medium textured eolian material (Eolian material B). Orthic and Brunisolic Gray Luvisols, and Orthic Humo-Ferric Podzols occur in minor amounts. Soils with luvisolic tendencies are especially evident on the drier slopes of eastern Banff and Jasper. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly expressed in the absence of Eolian material B. In some localities Ae horizons have been destroyed by recent surface modification processes such as avalanching, gullying, windthrow of trees, or shallow surface colluviation. Some gullies and depressional localities contain seeps where wet soils are found. Orthic and Cumulic Regosols occur on steep, colluviating portions of the landscape. Lithic soil phases are not common except on BY2X tracts where they dominate.

A pedon illustrating Orthic Eutric Brunisols of the BY2 Ecosite is described in Table 137 and shown in Color Plate 11. This pedon has a very thin eolian veneer and represents soils (of the BY2 Ecosite) with luvisolic tendencies occurring on relatively dry southwest aspects in eastern Banff. As in this case, the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t. is often associated with this kind of soil development on BY2. The relatively dark color of the Ck horizons is attributable to incorporation of material derived from Mesozoic strata.

Vegetation

The BY2 Ecosite is dominated by the Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30), and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.s. Overall, C13 is the most abundant v.t., but some BY2 tracts are dominated by C30 or C31. Factors affecting distribution of C13 versus C30 are not understood. The C31 v.t. tends to be more common on southerly aspects in the eastern part of the Front Ranges. The BY2 tracts characterized by C31 v.t.s often have soils with luvisolic tendencies. This soil - vegetation association implies somewhat drier conditions than on other BY2 soil - vegetation combinations.

Table 138 Stand (JD9082) illustrating the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t. of the BY2 Ecosite.

Small patches of Engelmann spruce-subalpine fir/false azalea (C14) and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) occasionally occur on northerly aspects of some tracts. Wet v.t.s such as Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) are associated with seeps. Snow avalanche v.t.s. such as subalpine fir-willow (S2) occur on avalanched portions of BY2 although the incidence of avalanching is less on BY2 than BY1. Fire affected vegetation in which spruce rather than pine is regenerating occurs in some areas (e.g. Upper Dormer Creek valley in Banff).

A stand representing vegetation of the pedon sample site described above (Table 137) and illustrating the C31 v.t. of BY2 is described in Table 138. The lower layers of this stand are shown in Plate 95. This stand has higher cover of *Shepherdia canadensis* and *Elymus innovatus* than the C31 central concept.

Discussion

The BY2 Ecosite is the dominant Bryant Ecosite of the Front Ranges although BY4 on valley floors and BY1 on northerly aspects may be associated in some areas.

Rather specific vegetation differences differentiate BY2 from BY1, landform genetic materials differentiate BY2 from BY4 (Table 134). The Moraine Lake 1 (ML1) and Cavell 2 (CA2) Ecosites resemble BY2 in terms of physiographic position, landform surface expression, and vegetation cover. However, ML1 occurs on morainal landforms consisting of noncalcareous, coarse textured till (Till A), and CA2 occurs on noncalcareous, medium textured till (Till B). Both ML1 and CA2 are dominated by Dystric Brunisols. The ML1 soils have significantly thicker sola.

BY4 - BRYANT 4 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BY4, occurs on glacial landforms consisting of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Inclined surfaces reflect the underlying bedrock. Hummocky surfaces reflect either underlying bedrock or deposition. The BY4 Ecosite is generally confined to valley floors including benchlands on broad valley floors and to lower valley wall slopes. BY4 is characterized by a soil pattern in which Eluviated Eutric Brunisols are dominant, Orthic Eutric Brunisols are subdominant. Vegetation cover is dominated by the Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/false azalea (C14) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.s. The C13 v.t. is most abundant but some BY4 tracts are dominated by C14 or C30. The BY4 Ecosite occurs in both Front and Main Ranges.

Geomorphology

The BY4 Ecosite is typified by glacial landforms consisting of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Surficial veneers of altered, medium textured eolian material (Eolian material B) are most extensive on BY4 tracts located in western Banff and southwestern Jasper and less extensive elsewhere. Calcareous, medium textured till (Till C) often underlies the ice-contact stratified material.

Topographically, the BY4 Ecosite displays irregularly shaped knolls and depressions of hummocky surfaces on valley floors and benchlands. Linear inclined slopes usually occur on lower valley walls above the valley floors. Bedrock control is responsible for the inclined slopes and sometimes for the hummocky surface expression. Occasionally, ridged surfaces that reflect underlying bedrock occur. The hummocky surface expression of ice contact deposits is often depositional in origin. Kettle-holes, kames, and eskers are outstanding depositional features that occur on some tracts mapped as BY4. In some BY4 tracts of lower valley wall slopes, hummocky depositional surfaces are superimposed upon inclined slopes that reflect the underlying bedrock surface. Failed slopes occur occasionally. Slopes commonly range from 5 to 45%. Erosional features, such as gullies on steep linear slopes and small glaciofluvial terraces, occur occasionally. Veneers of glacial drift and rock outcrops occur rarely except in BY4+R tracts where rock escarpments are relatively common.

Soils

Soils that characterize the BY4 Ecosite are dominated by Eluviated Eutric Brunisols. Orthic Eutric Brunisols are subdominant. These well drained soils have B horizons that range from the rudimentary textural horizons frequently associated with weathering of calcareous glacial material to the comparatively advanced Bm and Bf horizons associated with altered, medium textured eolian material (Eolian material B). Orthic and Brunisolic Gray Luvisols, and Orthic Humo-Ferric Podzols occur in minor amounts. Soils with luvisolic tendencies are especially evident on the drier slopes of eastern Banff and Jasper. Orthic Eutric Brunisols are significantly less abundant associated with BY4 than with BY2, and approximately equal in abundance on BY4 and BY1. Greater abundance of Eolian material B and more gentle slopes are favorable for Ae development on BY4 as opposed to BY2. The BY1 Ecosite has more exten-

sive veneers of Eolian material B but its usually steeper slopes result in more surface disturbances than on BY4. Some depressional localities affected by seepage have wet soils. Regosolic soils and lithic soil phases occur rarely. A pedon illustrating Orthic Eutric Brunisols of the BY4 Ecosite is described in Table 139 and shown in Color Plate 12. Plate 96 shows the sample site. Vegetation at this site is a seral stage of the Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.

Vegetation

The BY4 Ecosite is dominated by the Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/false azalea (C14), and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.s. Overall, C13 is the most abundant v.t., but some BY4 tracts are dominated by C14 or C30. Factors affecting distribution of C13 versus C30 are not understood. The C14 v.t. tends to be more common on more steeply sloping, northerly facing BY4 tracts in the Main Ranges. The accessory v.t., Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31), is quite common on some BY4 tracts located in the eastern part of the Front Ranges. This v.t. is often associated with soils having luvisolic tendencies. Wet v.t.s. such as Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) are associated with seepage in depressional localities. Snow avalanche v.t.s. such as subalpine fir-willow (S2) occur on avalanched portions of BY4 although the incidence of avalanching on BY4 is relatively low. Fire affected vegetation in which spruce rather than pine is regenerating occurs in some areas (e.g. upper Bryant Creek valley in Banff).

A stand illustrating the C30 v.t. of the BY4 Ecosite is described in Table 140. It is located <100 m downslope from the pedon sample site described above (Table 139). This stand has lower cover of *Empetrum nigrum* than is usual for C30.

Discussion

The BY4 Ecosite is the least extensive of the Bryant Ecosites and is not predominant in either the Front Ranges as is BY2 or Main Ranges as is BY1. Genetic material and landform surface expression differentiate BY4 from BY1 and BY2 as outlined in Table 134. The Panorama Ridge 6 (PR6) Ecosite has landforms and genetic material similar to BY4 but is differentiated because it is dominated by lodgepole pine forest occurring on soils with luvisolic tendencies. The Baker Creek 6 (BK6) Ecosite has similar landforms, genetic material, and vegetation on its upland (dry) segment but is differentiated from BY4 because it also includes about 30% wet depressions.

BZ - BRAZEAU ECOSECTION

The Brazeau (BZ) Ecosection is characterized by hummocky terrain comprised of noncalcareous, medium textured residuum (Residuum A) or calcareous, medium textured residuum (Residuum B) that occurs on valley walls and floors in the Lower Subalpine portion of the Subalpine Ecoregion. The BZ Ecosection is of very limited extent and occurs in areas underlain by failed Mesozoic strata in the Front Ranges. It is mapped only near Maligne and Brazeau Lakes in Jasper, and is dominated by lithic phases of Brunisolic soils associated with either Engelmann spruce-subalpine fir or lodgepole pine forests.

Table 141 General features of the Brazeau (BZ) Ecosites.

Ecosite	Landform	Soils	Vegetation
BZ1	Residuum A,B; hummocky	lithic phases of Brunisolic	Engelmann spruce-subalpine fir forest
BZ2	Residuum A,B; hummocky	lithic phases of Brunisolic	lodgepole pine forest

Two Ecosties (BZ1, BZ2) have been separated within the BZ Ecosection on vegetational differences as outlined in Table 141.

BZ1 - BRAZEAU 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BZ1, occurs on hummocky slopes comprised of noncalcareous, medium textured residuum (Residuum A) or calcareous, medium textured residuum (Residuum B). It is dominated by lithic phases of well drained Eluviated Dystric Brunisols and Eluviated Eutric Brunisols associated with the Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.s.

Two tracts of BZ1 are mapped, both in Jasper. One straddles a tributary of the Brazeau River near the outlet of Brazeau Lake and the other occurs at the northwest end of Maligne Lake. Both tracts are partially responsible for the damming that causes the lakes.

Geomorphology

The BZ1 Ecosite occurs on hummocky terrain comprised of noncalcareous, medium textured residuum (Residuum A) or calcareous, medium textured residuum (Residuum B). The Maligne Lake tract is dominated by noncalcareous, medium textured residuum; the Brazeau Lake tract by calcareous, medium textured residuum. These landforms consist of failed Mesozoic shale bedrock that now occupy valley floor positions. Bedding within the shaly parent material is present at depth. Shale content increases with depth to a lithic contact. Discontinuous veneers of altered, medium textured eolian material (Eolian material B) occur on BZ1. Slopes commonly range from 5 to 15%.

Soils

The BZ1 Ecosite is dominated by well drained lithic phases of Eluviated Dystric Brunisols and Eluviated Eutric Brunisols. These soils are developed on weathered Mesozoic shales and, because they reflect the nature of the bedrock, are variable in their chemical characteristics. Eluviated Dystric Brunisols are associated with noncalcareous, medium textured residuum (Residuum A) and Eluviated Eutric Brunisols with calcareous, medium textured residuum (Residuum B). Shale fragment content and size increases with depth to a lithic contact. Orientation of shaly coarse fragments in the weathering zone conforms to the original bedding planes of the underlying parent rock. A pedon described for BZ2 in Table 142 and shown in Color Plate 13 illustrates a lithic phase Eluviated Dystric Brunisol of the BZ1 Ecosite.

Vegetation

The BZ1 Ecosite is dominated by the mesic Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) v.t.s. The C30 v.t. occurs on the Maligne Lake BZ1 tract. The C31 v.t. dominates the Brazeau Lake BZ1 tract. A stand illustrating C31 of the BZ1 Ecosite is described in Table 143. The C30 and C31 v.t.s are thought to be fire remnants and are the main criteria for separating BZ1 from the lodgepole pine dominated BZ2.

Discussion

The BZ1 Ecosite is the least extensive of the two Brazeau Ecosites and is of very limited extent overall. Vegetational differences are the main criteria for separating BZ1 from BZ2 as outlined in in Table 141. In terms of physiographic position, landform surface expression, soils and vegetation, BZ1 most closely resembles the Ishbel 3 (IB3) Ecosite. The latter is distinguished because it is a landslide deposit with a heterogeneous mixture of soil and rock with many stones and boulders occurring in the weathering zone and on the surface. The BZ1 Ecosite also occurs on failed slopes but is differentiated by its uniform orientation of predominantly shaly coarse fragments in the weathering zone. It should be noted that shales are easily eroded by streams as evidenced by the shale escarpments below the outlet of Brazeau Lake.

BZ2 - BRAZEAU 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, BZ2, occurs on hummocky terrain comprised of noncalcareous, medium textured residuum (Residuum A) or calcareous, medium textured residuum (Residuum B). It is dominated by lithic phases of well drained Eluviated Dystric Brunisols and Eluviated Eutric Brunisols associated with the lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/Labrador tea (C29) v.t.s.

Four tracts of BZ2 are mapped, three occurring near Maligne Lake, and one near the outlet of Brazeau Lake. The two tracts of BZ2 at the outlet of Maligne Lake are largely responsible for the lake's existence.

Geomorphology

The BZ2 Ecosite occurs on hummocky terrain comprised of noncalcareous, medium textured residuum (Residuum A) or calcareous, medium textured residuum (Residuum B). The Maligne Lake tracts are dominated by noncalcareous, medium textured residuum, the Brazeau Lake tract by calcareous, medium textured residuum. These landforms consist of failed Mesozoic bedrock that now occupies valley wall and floor positions. Bedding is present within the shaly parent material at depth. Landslide deposits are often mapped adjacent to BZ2. Slopes are primarily complex and range from 15 to 45%. Shales on BZ2 are easily eroded by stream abrasion. Discontinuous surficial veneers of altered, medium textured eolian material (Eolian material B) occur on BZ2.

Soils

The BZ2 Ecosite is dominated by well drained lithic phases of Eluviated Dystric Brunisols and Eluviated Eutric Brunisols. These soils are developed on weathered shales and their chemical characteristics reflect the nature of the bedrock. The Eluviated Dystric Brunisols are associatd with noncalcareous, medium textured residuum (Residuum A), the Eluviated Eutric Brunisols with calcareous, medium textured residuum (Residuum B). Shale fragment content and size increases with depth to a lithic contact. Orientation of shaly coarse fragments in the weathering zone conforms to the original bedding planes of the underlying parent rock. Minor amounts of lithic phase Orthic Dystric Brunisols and Orthic Eutric Brunisols occur on steeper slopes. A pedon illustrating the lithic phase Eluviated Dystric Brunisol is described in Table 142 and shown in Color Plate 13. This pedon was sampled on a BZ2 tract adjacent to the outlet of Maligne Lake in Jasper.

Vegetation

The BZ2 Ecosite is dominated by the mesic lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/Labrador tea (C29) v.t.s. The C18 v.t. is primarily found on steeper tracts of BZ2. The C18 v.t. on the tract between Opal Hills and Maligne Lake is transitional to the Engelmann spruce-subalpine fir/grouseberry (C15) v.t. near the Upper Subalpine boundary. The C29 v.t. is primarily found on more gentle slopes. The vegetation plot description in Table 144 and shown in Plate 97 illustrates the C29 v.t. on BZ2 and represents the vegetation at the pedon sample site described above in Table 142.

Discussion

The BZ2 Ecosite is very limited in areal extent and occurs near Maligne and Brazeau Lakes in Jasper. It most closely resembles the Ishbel 1 (IB1) Ecosite in terms of physiographic position, landform surface expression, soils and vegetation. The two Ecosites are often mapped adjacent to each other. The IB1 Ecosite is distinguished because it occurs on landslide deposits with a heterogeneous mixture of soil and rock with many stones and boulders occurring in the weathering zone and on the surface. The BZ2 Ecosite also occurs on failed slopes but is differentiated by its uniform orientation of predominantly shaly coarse fragments in the weathering zone.

CA - CAVELL ECOSECTION

The Cavell Ecosection encompasses morainal landforms comprised of noncalcareous, medium textured till (Till B) in the Lower Subalpine portion of the Subalpine Ecoregion in Banff and Jasper. The CA Ecosection occurs most extensively in the Main Ranges in association with Precambrian Miette Group slates and shales. It also occurs in the Front Ranges in association with noncalcareous Mesozoic strata, and is found primarily on valley walls and floors including benchlands in broad valleys.

The dominant soils, Dystric Brunisols, are moderately developed and reflect the noncalcareous, medium textured parent material. Two groups of coniferous forest and a dry > wet pattern differentiate the three Cavell (CA) Ecosites (Table 145). Fig. 35 shows, schematically, the physiographic positions of the Cavell Ecosites and their relationship to other Ecosites.

CA1 - CAVELL 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, CA1, occurs on hummocky or ridged morainal landforms consisting of noncalcareous, medium textured till (Till B). Landform surface expression may be of depositional orgin or controlled by underlying bedrock. Its complex topography forms a compound landscape comprised of about 70% dry (well to moderately well drained, mesic) upland segments and 30% wet (poorly to very poorly drained, hygric to hydric) depressions between ridges and hummocks. Upland segments are characterized by a soil pattern in which Eluviated Dystric Brunisols are dominant, Orthic Dystric Brunisols subdominant. Vegetation of upland segments is dominated by the Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. The C14 v.t. occurs most often. Wet depressional segments contain a variety of pedogenically related wet soils best represented by the Orthic Gleysol, Rego Gleysol, Gleyed Ferro-Humic Podzol, and Terric Mesisol Subgroups. Vegetation of depressions is dominated by the spruce/Labrador tea/brown moss (O11), Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14), dwarf birch-shrubby cinquefoil-willow/brown moss (S1), and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s. O11 and O14 are most abundant.

Geomorphology

The CA1 Ecosite is typified by morainal landforms consisting of noncalcareous, medium textured till (Till B). In a few areas, e.g. upper Mistaya River valley near Peyto Lake in Banff and Athabasca Pass in Jasper, CA1 tracts include morainal landforms consisting of noncalcareous, coarse textured till (Till A). A medium textured variant of noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A), derived from slates and shales, dominates a few CA1 tracts of valley floors and lower slopes, e.g. upper Miette River valley in Jasper. Included in this glacial material are the abandoned side glacial stream channels described by Rutter (1972) that occur near Eisenhower Junction in Banff. Surface veneers

of altered, medium textured eolian material (Eolian material B) occur extensively on CA1 tracts of western Banff and southwestern Jasper and sporadically elsewhere. Redeposited Eolian material B plus eroded till as thin veneers of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) occurs in channeled depressions. Mineral soil materials of wet depressions are usually thinly mantled by peat derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally, wood fragments may be found. Where the peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b), recognizing that in some localities fen vegetation has been succeeded by open forest.

Topographically, CA1 displays irregular hummocky or ridged slopes on valley floors including benchlands and on lower valley wall slopes. Occasionally, CA1 occurs on valley shoulders. Slopes commonly range from 5 to 45%. Hummocky and ridged surfaces reflect underlying bedrock surfaces, glacial deposition, or postglacial slope failure. Failed till slopes on CA1 tracts are usually seepage-induced rotational slumps, but remnant rock glacier landforms also occur. Slope failure status may be active or inactive. Morainal veneers occur infrequently except on CA1X (e.g. Miette River valley near Rink Brook in Jasper) where they dominate. Bedrock outcrops occur occasionally.

Soils

Soils of the CA1 Ecosite are distributed in a pattern governed by drainage conditions. Soils of the well to moderately well drained upland segments are distributed in a secondary pattern reflecting degree of eluvial (Ae) horison development. Eluviated Dystric Brunisols are dominant; Orthic Dystric Brunisols subdominant. These soils have B horizons that range from moderately developed Bm horizons at the till surface to the comparatively advanced B, and Bf horizons associated with altered, medium textured eolian material (Eolian material B) veneers. Genetically related Orthic Humo-Ferric Podzols, with podzolic Bf horizons above the parent material disconformity, are important accessory soils. These are most abundant on CA1 tracts with extensive Eolian material B veneers. Soils with Bhf horizons occur in minor amounts.

Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly developed in the absence of Eolian material B. In some localities, recent surface disturbances such as windthrow of trees, sheet erosion, and soil creep have inhibited or destroyed Ae horizon development. Many CA1 upland soils display, in their lower sola and upper C horizons, clay films that are thought to be formed by pressure (e.g. freeze-thaw). Lithic soil phases are associated with morainal veneers and dominate on CA1X tracts. The pedons described in Tables 148 and 150 for the CA2 and CA4 Ecosites illustrate the upland soils of CA1.

A variety of pedogenically related soils occur on the poorly to very poorly drained depressional segments of CA1. These are best represented by the Orthic Gleysol, Rego Gleysol, Gleyed Ferro-Humic Podzol, and Terric Mesisol Subgroups. The amount of gleying, reflecting degree of movement and aeration of seepage waters, is variable. The accessory soils, Gleyed Dystric Brunisols, occur on sites where gleying is weakly expressed. Prolonged periods of saturation give strongly gleyed soils with little or no pedogenic horizonation (Rego Gleysols). In some localities, recent or continuing fluvial activity has inhibited horizon development and organic matter accumulation. Orthic Gleysols and Gleyed Ferro-Humic Podzols occur in localities with shorter periods of saturation. Additionally, the presence of eolian or fluviolacustrine veneers promotes the development of iron, aluminum, and humus enriched B and podzolic B horizons (usually Bhf and podzolic Bhf). Favorable moisture, nutrient, and vegetation conditions have resulted in the accumulation of varying thicknesses of fen peat on most depressional soils. Terric Mesisols occur where the peat is >40 cm thick. Other Organic soils with subdominant humic or fibric layers, Gleyed Eluviated Dystric Brunisols, and Humic Gleysols occur occasionally.

A pedon illustrating gleyed Podzolic soils of CA1 wet segments is described in Table 146. Plate 98 shows the sample site. This pedon has a podzolic Bh horizon with high pyrophosphate extractable iron and aluminum. It has developed in Eolian material B immediately above the till. The presence of Bhf and podzolic Bhf horizons tend to be more common in this setting. The low amount of calcium carbonate in this profile is attributed to groundwater discharge.

Vegetation

Vegetation of the CA1 Ecosite is distributed in a pattern governed by drainage conditions. The Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s dominate the well to moderately well drained upland segments. The C14 v.t. is the most abundant v.t. but on some tracts C13 or C21 dominate upland segments. The C13 v.t. occurs more often at low elevations on gentle slopes and in central and eastern areas of both parks. In northern Jasper and along

the Continental Divide, C21 sometimes replaces C14. Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) occur in minor amounts in central to eastern areas. In areas where fire has been a factor, lodgepole pine forest, best represented by the moist lodgepole pine/false azalea/grouseberry (C20) and lodgepole pine/Labrador tea (C29) v.t.s, is important. Lodgepole pine/buffaloberry/grouseberry (C18) also occurs occasionally. Modification of these spruce and pine v.t.s. by recent fires has occurred in some areas which are mapped as CA1B, e.g. upper Mistaya River valley in Banff. Occasionally, modification by avalanching occurs.

Vegetation of depressional segments, dominated by the spruce/Labrador tea/brown moss (O11), Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14), dwarf birch-shrubby cinquefoil-willow/brown moss (S1), and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s, reflects poor drainage. The O11 and O14 v.t.s. are most abundant but S1 and S3 dominate some of the more gently sloping benches and depressions within CA1 tracts. Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6) is an accessory v.t. and occurs on gently sloping localities with fluvial and organic deposits. Engelmann spruce-subalpine fir/valerian-fleabane (O9) and water sedge-beaked sedge (H11) occur in minor amounts. A plot illustrating S1 on

wet depressional segments of CA1 is described in Table 147. This plot is located on the same tract as the pedon sample site described above (Table 146).

Discussion

The CA1 Ecosite encompasses a compound landscape pattern consisting of well drained upland segments similar to the Cavell 2 (CA2) Ecosite and poorly to very poorly drained depressional segments similar to the Consolation Valley 1 (CV1) and, occasionally, Hector 1 (HC1) or Hector 4 (HC4) Ecosites. The proportion of wet depressions on CA1 commonly ranges from 20 to 40%. Map presentation of CA1 tracts at scales larger than 1:50,000 is invalid because at these scales the upland and wet segments become mappable as separate Ecosites. In terms of physiographic position, landform surface expression, and vegetation cover, CA1 resembles the Baker Creek 6 (BK6) Ecosite. However, BK6 is distinguished because it occurs on glacial landforms consisting of calcareous, medium textured till (Till C) and calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Upland segments of BK6 are dominated by Eutric Brunisols. The CA1 Ecosite is the only Cavell Ecosite with a dry > wet pattern (Table 145). The Egypt 3 (EG3) Ecosite is the Upper Subalpine counterpart of CA1.

CA2 - CAVELL 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, CA2, occurs on morainal blankets consisting of noncalcareous, medium textured till (Till B) overlying inclined bedrock on valley walls. These well drained soils normally occur in a pattern reflecting the degree of eluvial (Ae) horizon development. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant. Vegetation cover is dominated by the Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. C14 is most abundant.

Geomorphology

The CA2 Ecosite is typified by morainal blankets overlying inclined bedrock. The moraines consist of noncalcareous, medium textured till (Till B). Surface veneers of altered, medium textured eolian material (Eolian material B) occur extensively on CA2 tracts of western Banff and southwestern Jasper and sporadically elsewhere. Colluvium derived from till and fractured bedrock is found occasionally on the steepest portions of the landscape. A medium textured variant of noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A), derived from slates and shales, occurs occasionally on valley floors and lower slopes.

Topographically, CA2 displays long, linear slopes consisting of till blankets mantling the inclined bedrock that forms valley walls. Slopes commonly range from 15 to 70%. Gullied slopes occur, but much less frequently than on the Bryant 1 and 2 (BY1, BY2), and Moraine Lake 1 (ML1) Ecosites. Colluvial blankets and veneers occur locally on the steepest terrain, particularly below bedrock escarpments. Tracts of CA2 situated along valley bottoms and shoulders, at valley confluences, in cirque basins and cols, and on failed slopes often display morainal landforms with irregular surfaces and complex topography (5-45% slopes). These landforms include morainal blankets and veneers overlying ridged and hummocky bedrock and the relatively deep till of hummocky moraines. Morainal veneers also occur on linear, inclined slopes and are dominant on tracts mapped as CA2X. Bedrock outcrops occur occasionally but are particularly common on CA2+R tracts.

Soils

The CA2 Ecosite is characterized by a pattern of soils that reflects the degree of eluvial (Ae) horizon development. Eluviated Dys-

tric Brunisols are dominant and Orthic Dystric Brunisols subdominant. These well to moderately well drained soils have B horizons that range from moderately developed Bm horizons, at the till surface, to the strongly developed Bm and Bf horizons associated with altered, medium textured eolian (Eolian material B) veneers. Genetically related Orthic Humo-Ferric Podzols, with Bf horizons in the eolian material above the parent material disconformity, are important accessory soils. Soils with Bhf horizons occur in minor amounts. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly developed in the absence of Eolian material B. In some localities, recent surface disturbances such as windthrow of trees, avalanching, sheet erosion, and soil creep have inhibited or destroyed Ae horizon development. Many CA2 soils display, in their lower sola and upper C horizons, clay films that are thought to be formed by pressure (e.g. freeze-thaw) rather than illuviation. Other soils occurring in small amounts are wet soils on seeps of depressional localities and Regosolic soils on steep, colluviating portions of the landscape. Lithic soil phases occur sporadically on CA2 but dominate on tracts mapped as CA2X.

A pedon illustrating Eluviated Dystric Brunisols of CA2 is described in Table 148. The upper part of the till parent material is more heterogeneous than normal for CA2 soils and is attributed to minor stratification. Sandy loam textures and quartzite fragments within the till reflect incorporation of material derived from Gog Group quartzites that dominate the upper reaches of Portal Creek valley in Jasper. Material derived from Miette Group slates and shales, that dominate the lower reaches of Portal Creek valley and underlie till at the sample site, is the major constituent of the till.

Vegetation

Vegetation of the CA2 Ecosite is dominated by the Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. The C14 v.t. is most abundant but on some tracts C13 or C21 dominates. The C14 v.t. occurs rarely in eastern Banff and Jasper. The C13 v.t. occurs more often at low elevations, on gentle slopes and in central to eastern areas of both parks. In northern Jasper and along the Continental Divide, C21 sometimes replaces C14 as the dominant v.t. Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) and Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) occur in minor amounts in central and eastern areas. Snow avalanche v.t.s, such as subalpine fir-willow (S2), occur on avalanched portions of the landscape. Fire affected vegetation, in which spruce is regenerating, occurs in some areas (e.g. north of Cascade Mountain in Banff). A plot representing vegetation of the pedon sample site and illustrating C14 on CA2 is described in Table 149.

Discussion

The CA2 Ecosite is the most extensive of the Cavell Ecosites. In terms of physiographic position, landform surface expression, and vegetation, CA2 resembles the Bryant 1 and 2 (BY1, BY2), and Moraine Lake 1 (ML1) Ecosites. However, BY1 and BY2 occur on morainal landforms consisting of calcareous, medium textured till (Till C), and ML1 occurs on noncalcareous, coarse textured till (Till A) whereas CA2 occurs on Till B. Also BY1 and BY2 are dominated by Eutric Brunisols. The ML1 Ecosite is characterized by Dystric Brunisols with thicker sola and Ae horizons than CA2 soils. The CA2 is differentiated from other Cavell Ecosites by vegetation differences and amount of wet, seepage-affected landscape as outlined in Table 145. The Egypt 1 (EG1) Ecosite is the Upper Subalpine counterpart of CA2.

CA4 - CAVELL 4 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, CA4, occurs on morainal blankets consisting of noncalcareous, medium textured till (Till B) overlying inclined bedrock on valley walls. The soils normally occur in a pattern reflecting the degree of eluvial (Ae) horizon development. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant. Vegetation cover is dominated by the lodgepole pine/buffaloberry/twinflower (C19) and lodgepole pine/false azalea/grouseberry (C20) v.t.s. The CA4 Ecosite is more extensive in Jasper than in Banff.

Geomorphology

The CA4 Ecosite is typified by morainal blankets overlying inclined bedrock. The moraines consist of noncalcareous, medium textured till (Till B). Veneers of altered, medium textured eolian material (Eolian material B) occur sporadically and are very thin. Erosion following fires appears to have removed the eolian veneer from many tracts. The few CA4 tracts in the Bow River valley in Banff have more extensive Eolian material B veneers. Colluvium derived from till and fractured bedrock occurs occasionally on the steepest portions of the landscape. A medium textured variant of noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A), derived from slates and shales, occurs occasionally on valley floors and lower slopes.

Topographically, CA4 displays long, linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes commonly range from 15 to 70%. Gullied slopes occur associated with CA4 but much less frequently than with Panorama Ridge 1 and 2 (PR1, PR2) and Moraine Lake 2 (ML2) Ecosites. Colluvial blankets and veneers occur locally on the steepest terrain (>60%), particularly below bedrock escarpments. Tracts of CA4 situated along valley bottoms and shoulders, at valley confluences, in cirque basins and cols, and on failed slopes often display morainal landforms with irregular surfaces and complex topography (5-45% slopes). These landforms include morainal blankets and veneers overlying ridged and hummocky bedrock and the relatively deep till of hummocky moraines. Morainal veneers also occur on linear, inclined slopes and are dominant on tracts mapped as CA4X. Bedrock outcrops occur occasionally but are particularly common on CA4+R tracts.

Soils

The soils of the CA4 Ecosite are distributed in a pattern that reflects the degree of eluvial (Ae) horizon development. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant. These well drained soils have B horizons that range from moderately developed Bm horizons, at the till surface, to the strongly developed Bm and, infrequently, Bf horizons associated with altered, medium textured eolian (Eolian material B) veneers. Podzolic soils, generally Orthic Humo-Ferric Podzols, occur infrequently and are most common on CA4 tracts of western Banff. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly developed in the absence of Eolian material B. In some localities, recent surface disturbances such as windthrow of trees, avalanching, sheet erosion, and soil creep have inhibited or destroyed Ae horizon development. Many CA4 soils display, in lower sola and upper C horizons, clay films thought to be formed by pressure (e.g. freeze-thaw) rather than by illuviation. Other soils occurring in small amounts are wet soils on seeps of depressional localities and Regosolic soils on steep colluviating portions of the landscape. Lithic soil phases occur sporadically on tracts mapped as CA4 but dominate on CA4X tracts. A pedon illustrating Eluviated Dystric Brunisols of CA4 is described in Table 150.

Vegetation

Vegetation of the CA4 Ecosite is dominated by the lodgepole pine/buffaloberry/twinflower (C19) and lodgepole pine/false azalea/grouseberry (C20); v.t.s that reflect complex fire and successional histories within the Lower Subalpine. Lodgepole pine/green alder/feathermoss (C10) and lodgepole pine/buffaloberry/grouseberry (C18) are accessory v.t.s, with C10 occurring most often on cool, moist, northerly aspects at low elevations. Lodgepole pine/juniper/bearberry (C3) on subxeric sites, lodgepole pine/buffaloberry/showy aster

Discussion

In terms of physiographic position, landform surface expression, and vegetation, CA4 resembles the Panorama Ridge 1 and 2 (PR1, PR2), and Moraine Lake 2 (ML2) Ecosites. However, PR1 and PR2 occur on morainal landforms consisting of calcareous, medium textured till (Till C), and ML2 occurs on noncalcareous, coarse textured till (Till A) whereas CA4 occurs on Till B. The PR1 and PR2 Ecosites are dominated by Eutric Brunisols that display luvisolic tendencies. The ML2 is characterized by Dystric Brunisols with thicker sola and Ae horizons than CA4 soils. The CA4 Ecosection is differentiated from other Cavell Ecosites by vegetation differences and amount of wet, seepage-affected landscape as outlined in Table 145.

CN - CYCLONE ECOSECTION

The Cyclone (CN) Ecosection occurs on linear fluvial landforms comprised of either noncalcareous, coarse, stratified fluvial material (Fluvial material A) or calcareous, coarse, stratified fluvial material (Fluvial material B). Modification by snow avalanching and channeling is a common feature. The CN Ecosection is dominated by Regosolic soils associated with dry and moist shrub thickets.

The CN Ecosection occurs on lower slopes and valley floors in the Upper Subalpine portion of the Subalpine Ecoregion in both parks, mainly within the Front Ranges.

Only one Ecosite (CN1) is recognized within the CN Ecosection. Table 152 outlines the general features of the Cyclone 1 (CN1) Ecosection. Fig. 53 for the Tyrrell Ecosection shows the position of CN1 on the landscape.

CN1 - CYCLONE 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, CN1, is characterized by fluvial fans and aprons comprised of either noncalcareous, coarse, stratified fluvial material (Fluvial material A), or calcareous, coarse, stratified fluvial material (Fluvial material B). Modification by snow avalanching and channeling is common. Well to moderately well drained Orthic Regosols are most abundant. Vegetation is characterized by the willow-dwarf birch-shrubby cinquefoil (S10) and willow/hairy wild rye (S12) v.t.s.

Geomorphology

The CN1 Ecosite is characterized by fluvial fans and aprons comprised of either noncalcareous, coarse, stratified fluvial material (Fluvial material A) or calcareous, coarse, stratified fluvial material (Fluvial material B). Landforms comprised of Fluvial material B are more common. Modification by snow avalanching and channeling is common. The CN1 Ecosite is geomorphologically active and is subject to episodic flooding. Floodplains, terraces, and blankets are included on some CN1 tracts. Fluvial blankets usually overlie colluvial aprons and fans.

Topographically, CN1 is a gently sloping landform with linear slopes commonly ranging from 5 to 45%. Slopes <5% occur on fluvial floodplains and terraces.

Table 152 General features of the Cyclone 1 (CN1) Ecosite.

Ecosite	Landform	Soils	Vegetation

Soils

Well to moderately well drained soils with little or no genetic horizon development dominate the CN1 Ecosite. Orthic Regosols are most abundant but a few tracts mapped as CN1 are dominated by Cumulic Regosols and Orthic Humic Regosols. These soils reflect incorporation of humus and modification by fluvial accretion. Geomorphic surfaces associated with Orthic Humic Regosols have remained stable long enough for development of relatively thick Ah horizons. The closely related Cumulic Humic Regosols occur in minor amounts. Ah horizon development has been interrupted by episodic flooding and fluvial aggradation in Cumulic Regosols. Orthic Eutric Brunisols are accessory soils that usually occupy slightly elevated, infrequently flooded portions of the landscape. Small amounts of gleyed soils occur where water tables are high along the lower margins of fans and aprons and on floodplains. A pedon illustrating Cumulic Regosols of CN1 is described in Table 153 and shown in Color Plate 14. This pedon was sampled in the upper Panther River valley in Banff. The dark colored horizons in this pedon are inherited from the dark colored shaly Mesozoic strata that occur upslope.

Vegetation

A variety of shrub dominated v.t.s and intergrades occur on tracts of CN1. They are best represented by the willow-dwarf birch-shrubby cinquefoil (S10) and willow/hairy wild rye (S12) v.t.s. The accessory v.t.s. willow-dwarf birch/fleabane (S4) and willow/cinquefoil (S8) occur and are probably associated with seasonally high water tables. Small amounts of the Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) and dwarf birch-willow/kobresia (S9) v.t.s occur on some tracts. A plot illustrating the willow/hairy wild rye (S12) v.t. of the CN1 Ecosite is described in Table 154 and shown in Plate 60 and represents the vegetation at the pedon sample site described in Table 153.

Discussion

The CN1 Ecosite most resembles the Num-Ti-Jah 2 (NT2) Ecosite but the latter is differentiated by having imperfectly to poorly drained soils. The CN1 Ecosite may also appear to have similar vegetation to the Tyrrell 1 (TR1) Ecosite but the latter is differentiated by having better developed soils occurring on morainal deposits. The TR1 Ecosite is often mapped adjacent to CN1. Pipestone 6 and 7 (PP6, PP7) are the Lower Subalpine counterparts of CN1.

CP - COPPER ECOSECTION

The Copper (CP) Ecosection is characterized by inclined, hummocky, and ridged terrain comprised of noncalcareous, medium textured residuum (Residuum A) derived from Miette Group strata in the Main Ranges and from Mesozoic strata in the Front Ranges. Some tracts of CP occur on failed bedrock. It is dominated by lithic Dystric Brunisols and Engelmann spruce-subalpine fir open and closed forests and subalpine larch-subalpine fir forest. The CP Ecosection occurs primarily on valley shoulders and spurs in the Upper Subalpine portion of the Subalpine Ecoregion in both parks.

Only one Ecosite (CP1) is recognized within the CP Ecosection and its general features are outlined in Table 155. Fig. 36 shows the CP1 Ecosite on the landscape in relation to other Ecosites.

Table 155 General features of the Copper 1 (CP1) Ecosite.

Ecosite	Landform	Soils	Vegetation

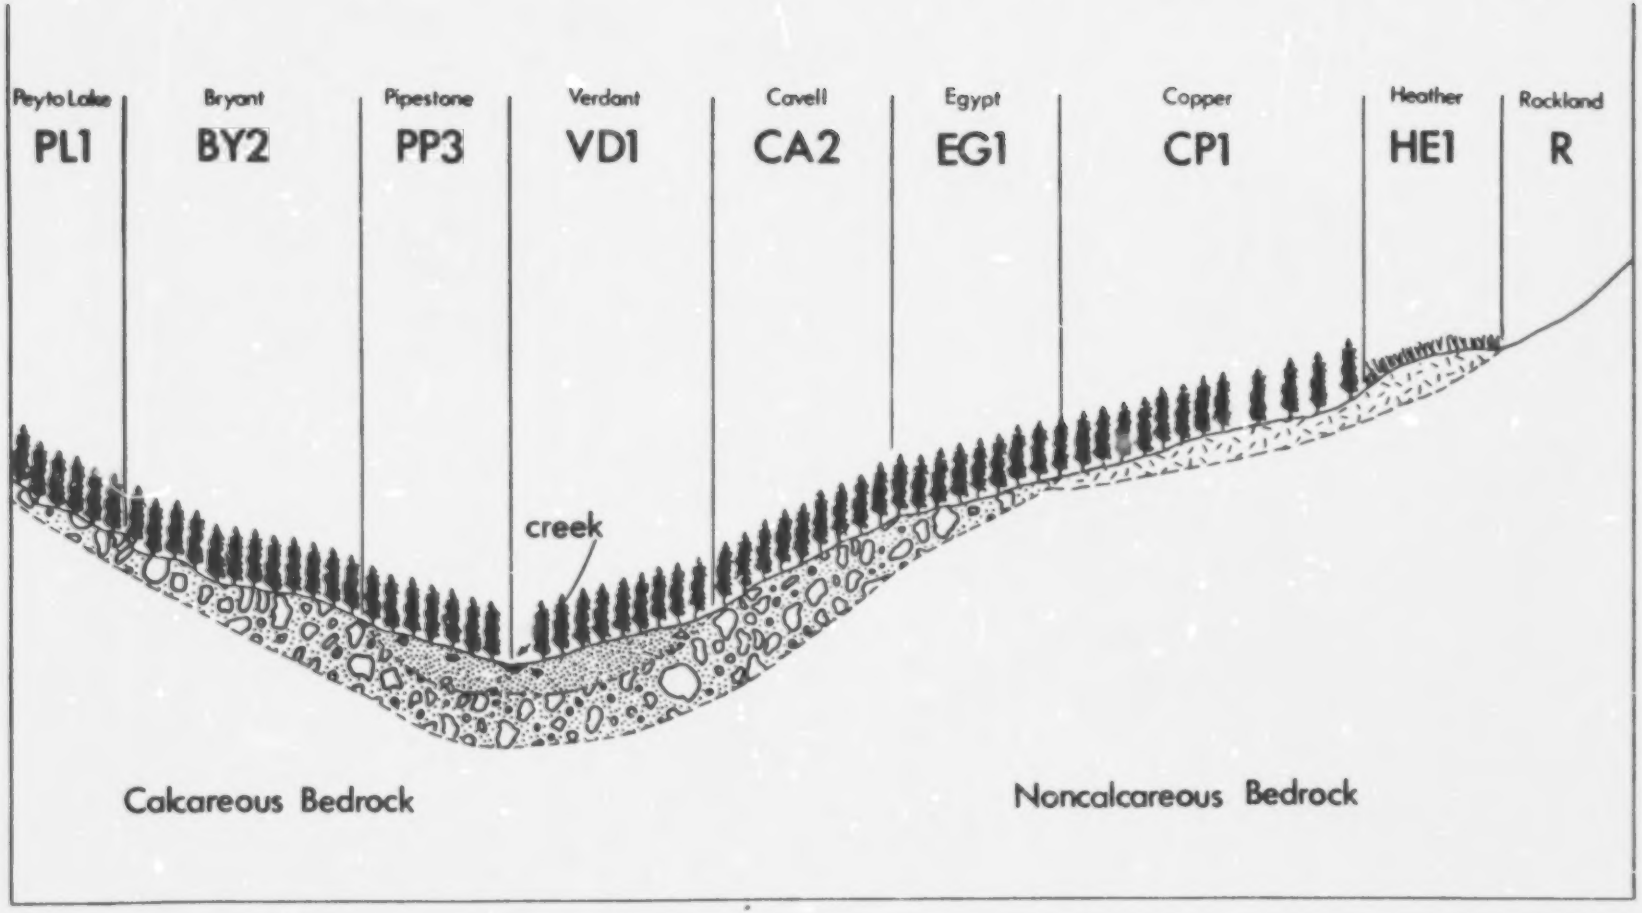
Figure 36 Landscape schematic showing the relationships of the Copper 1 (CP1) Ecosite to other Ecosites.



CP1 - COPPER 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, CP1, occurs on inclined, hummocky, and ridged terrain comprised of noncalcareous, medium textured residuum (Residuum A) derived from Miette Group strata in the Main Ranges and from Mesozoic strata in the Front Ranges subprovince. Some tracts of CP1 occur on failed bedrock. The CP Ecosite is dominated by well to moderately well drained lithic phases of Orthic and Eluviated Dystric Brunisols. Vegetation is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15) and Engelmann spruce-subalpine fir/heather (O10) and subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t.s.

Geomorphology

The CP1 Ecosite occurs on inclined, hummocky, and ridged terrain comprised of noncalcareous, medium textured residuum (Residuum A). This residuum is derived from either the Miette Group in the Main Ranges or Mesozoic strata in the Front Ranges. The residuum weathers in situ with soils developing at the surface. Coarse fragment content increases with depth, usually to a lithic contact. Surficial veneers of altered, medium textured eolian material (Eolian material B) occur on CP1 in western Banff and sporadically elsewhere. Till erratics occur on some tracts.

Topographically, CP1 displays linear slopes on inclined terrain and complex slopes on hummocky and ridged terrain. Slopes commonly range between 15 and 60%. Hummocky terrain is more common on tracts of CP1 that are failed. These tracts have similar surface expression to landslides and old rock glaciers.

Soils

The soils of the CP1 Ecosite develop from weathered shales and slates. They reflect the noncalcareous nature and medium and fine texture of these lithologies. The CP1 Ecosite is characterized by well to moderately well drained, lithic phase Orthic and Eluviated Dystric Brunisols. Orthic Dystric Brunisols are dominant on most tracts. These soils are similar but separated taxonomically on thickness of the surface eluvial (Ae) horizon. Where altered, medium textured eolian material is present, Eluviated Dystric Brunisols and Orthic Humo-Ferric Podzols occur. Shale and slate fragment content and size increases with depth to a lithic contact. Orientation of the fragments in the weathering zone conforms to the original bedding planes of the underlying parent rock. Table 156 describes a pedon sampled in lower Pharoah Creek valley in Banff that illustrates an Orthic Dystric Brunisol of the CP1 Ecosite. Color Plate 15 shows this pedon.

Vegetation

The CP1 Ecosite is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/heather (O10), and subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t.s. C15 and O10 are the most abundant v.t.s. The C23 v.t. dominates on a few tracts of CP1 in southern Banff. Minor amounts of the heather-everlasting (L5) and Engelmann spruce-subalpine fir/heather/feathermoss (C34) v.t.s also occur. A stand illustrating the C15 v.t. of the CP1 Ecosite is described in Table 157 and shown in Plate 99 and represents vegetation at the pedon sample site described above in Table 156.

Table 158 General features of the Consolation Valley 1 (CV1) Ecosite.

Ecosite	Landform	Soils	Vegetation
CV1	Till A,B,C; blanket > sloping fen	Wet[80]: Gleysolic, gleyed Podzolic, Organic Dry[20]: Eutric and Dystric Brunisol	Wet[80]: wet spruce open forest, wet Engelmann spruce-subalpine fir open forest > wet shrubby meadow, birch fen Dry[20]: Engelmann spruce-subalpine fir forest, lodgepole pine forest

Discussion

The CP1 Ecosite most closely resembles the Whitehorn 2 (WH2) and Endless Chain 1 (EN1) Ecosites in terms of landform surface expression, soils, and vegetation. However, WH1 and EN1 occur on Colluvium B and A respectively and distinguishes them from CP1 which occurs on Residuum A. The CP1 Ecosite may also resemble Whitehorn 1 (WH1) in southern Banff where the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. occurs but can be distinguished by the colluvial material associated with the latter. Failed tracts of CP1 may appear similar to Boulder Pass 1 and 2 (BP1, BP2) Ecosites but the latter occur on landslide materials. The Brazeau 1 and 2 (BZ1, BZ2) are the Lower Subalpine counterparts of CP1.

CV - CONSOLATION VALLEY ECOSECTION

The Consolation Valley Ecosection is complex and encompasses dominantly wet, seepage affected, morainal landforms throughout the Lower Subalpine portion of the Subalpine Ecoregion in Banff and Jasper. Inclined, ridged, and hummocky surface expressions are characteristic and reflect bedrock control, glacial deposition, or slope failure. The moraines consist of noncalcareous, medium textured till (Till B), the low lime phase of calcareous, medium textured till (Till C), and occasionally, noncalcareous, coarse textured till (Till A). The subdominant landforms consist of sloping fens that thinly mantle the till on the wettest localities. A wet-dry landscape pattern governed by drainage and seepage conditions is characteristic. This pattern is comprised of about 80% wet (poorly to very poorly drained, hygric to hydric) segments and 20% dry (well to moderately well drained, mesic) segments.

A complex set of genetically related Gleysolic, gleyed Podzolic, and Organic soils occur on the wet segments. Distribution of these soils is related to degrees of gleying and saturation, and the presence of primary mineral-bearing surface veneers. Wet Engelmann spruce-subalpine fir open forest, wet spruce open forest, wet shrubby meadow, and birch fen best characterize the vegetation of CV1 wet segments. The open forest vegetation is most extensive. Brunisolic soils occurring under Engelmann spruce-subalpine fir or lodgepole pine forests dominate the dry segments. Table 158 summarizes the characteristics of the one Consolation Valley Ecosite (CV1).

The CV Ecosection normally occurs on the floors and adjacent lower slopes of narrow valleys and on lower valley walls and adjacent upper benchland slopes in broad valleys (Figure 37). These positions correspond to major zones of groundwater discharge within a valley hydrologic system. Wetness is attributed to water supply rather than to poor soil permeability as exemplified in the Merlin Castle (MC) Ecosection. Seeps and seepage are characteristic and occur throughout the thaw season. Dry segments occupy localities where the fluctuating water table rarely reaches the control section.

The CV Ecosection is more extensive in the Main Ranges than in the Front Ranges. In the Front Ranges it usually occurs on broad valley floor benchlands where the unconsolidated glacial deposits are underlain by Mesozoic shales and sandstone. In the Main Ranges, CV usually occurs on lower valley wall slopes and valley floors including benchlands where the glacial deposits are underlain by the Miette Group slates and shales. Groundwater flow patterns appear to be affected by these strata, thus contributing to high water tables and seepage.

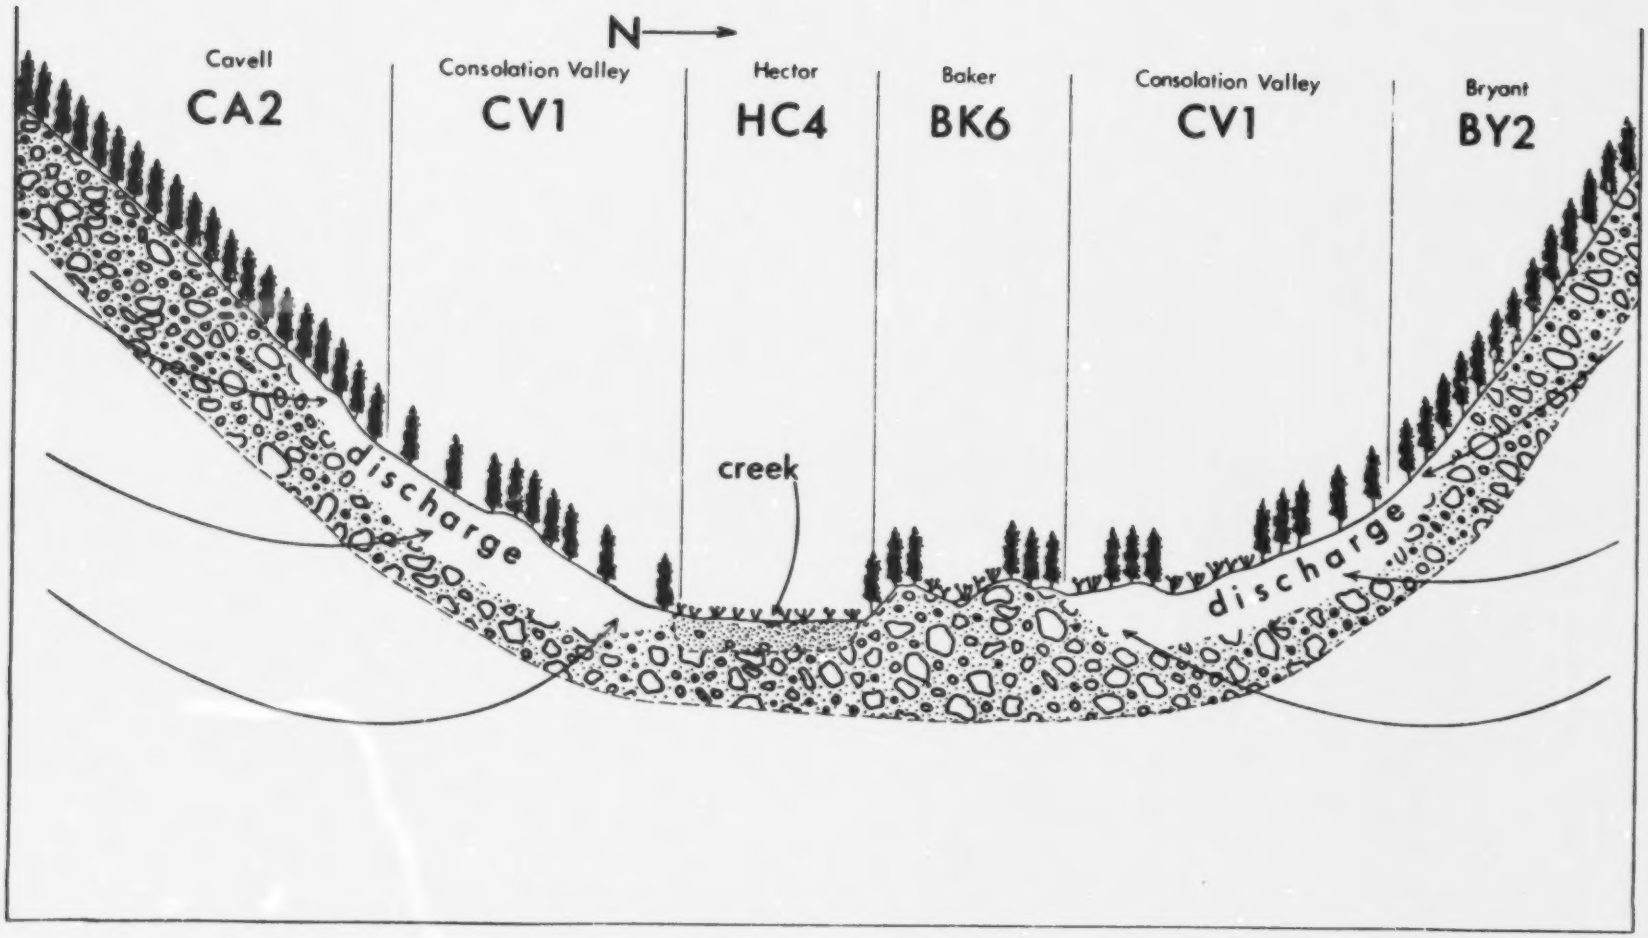
CV1 - CONSOLATION VALLEY 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, CV1, encompasses dominantly wet, seepage affected morainal landforms displaying inclined, ridged, or hummocky surfaces. These moraines consist of noncalcareous, medium textured till (Till B), the low lime phase of calcareous, medium textured till (Till C), and occasionally, noncalcareous, coarse textured till (Till A). Inclined surfaces usually reflect the underlying bedrock. Hummocky and ridged surfaces reflect bedrock control, glacial deposition, or post depositional slope failure. The subdominant landform consists of sloping fens that thinly mantle the till on the wettest localities. A wet > dry landscape pattern governed by drainage and seepage conditions is characteristic. This pattern is comprised of about 80% wet (poorly to very poorly drained, hygric to hydric) segments and 20% dry (well to moderately well drained, mesic) segments.

A complex set of genetically related soils, best represented by the Orthic Gleysol, Rego Gleysol, Gleyed Ferro-Humic Podzol, and Terric Mesisol Subgroups, occurs on the wet segments. Distribution of these soils is related to degrees of gleying and saturation, and the presence of mineral surface veneers. Vegetation of wet segments is also complex and is best represented by a pattern in which the spruce/Labrador tea/brown moss (O11) and Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) v.t.s are dominant, and the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s are subdominant. Eluviated Eutric Brunisols or Elu-

Figure 37 Landscape schematic showing the relationship of the Consolation Valley 1 (CV1) Ecosite to other Ecosites.



viated Dystric Brunisols dominate the dry segments. This soil distribution is governed by calcareousness and reaction of the parent material. Spruce or lodgepole pine forest, best represented by the Engelmann spruce-subalpine fir/feathermoss (C13), lodgepole pine/false azalea/grouseberry (C20), and lodgepole pine/Labrador tea (C29) v.t.s, dominate the dry segments.

Geomorphology

The CV1 Ecosite is typified by morainal landforms consisting of noncalcareous, medium textured till (Till B), the low lime (weakly to moderately calcareous) phase of calcareous, medium textured till (Till C), and in a few areas, noncalcareous, coarse textured till (Till A). The higher lime end member of Till C also occurs occasionally. Glacial landforms consisting of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) or, rarely, noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) are important along some valley floors (e.g. east end of Shadow Lake in Banff). Parent material textures are predominantly medium (silt loam to loam to sandy loam) and less frequently coarse (sandy loam to loamy sand to sand), or fine (clay loam to silty clay loam to silty clay). Wet segments are usually thinly mantled by peat derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally wood fragments may be found. Where the peat is >40 cm thick, the landform is classified as sloping fen (C.S.S.C. 1978b) recognizing that in some localities fen vegetation has been succeeded by open forest. Within the control section the fen peat is underlain by till, or occassionally, by noncalcareous, coarse, stratified fluvial material (Fluvial material A), calcareous, coarse, stratified fluvial material (Fluvial material B), altered, medium textured eolian material (Eolian material B), or altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) veneers. The fluvial and fluviolacustrine veneers may contain reworked material originally deposited as Eolian material B veneers. On some sites, Eolian material B containing ash is preserved in thin layers at or near the base of the organic layer. Eolian material B veneers also occur on the dry segments and are most extensive in western Banff and southwestern Jasper. The unconsolidated materials of CV1 are usually underlain, at variable depth, by Precambrian or Mesozoic strata.

Topographically, CV1 displays linear (inclined) to irregular (hummocky or ridged) slopes on lower valley walls and valley floors including benchlands. Slopes commonly range from 5 to 45%. Inclined slopes generally reflect the underlying bedrock surfaces. Hummocky and ridged surfaces reflect underlying bedrock surfaces, glacial deposition, or post depositional slope failure. Failed till slopes on CV1 tracts are usually seepage-induced rotational slumps. Extinct rock glaciers and apron-like landforms consisting of till that has undergone flow (e.g. lower slopes of Bow River valley near Mosquito Creek in Banff) also occur. Slope failure status may be active or inactive. Morainal veneers and bedrock outcrops rarely occur.

Soils

Soils of the CV1 Ecosite are distributed in a pattern governed by drainage and seepage conditions. A complex set of pedogenically related soils, best represented by the Orthic Gleysol, Rego Gleysol, Gleyed Ferro-Humic Podzol, and Terric Mesisol Subgroups, occurs on the wet segments. Strength of gleying, reflecting degree of movement and aeration of seepage waters, is variable. The accesory soils, Gleyed Eutric Brunisols and Gleyed Dystric Brunisols, occur on sites where gleying is weakly expressed. Prolonged periods of saturation give strongly gleyed soils with little or no pedogenic horizonation (Rego Gleysols). In some localities, recent or continuing fluvial and soil flow activities have inhibited or destroyed horizon development. Orthic Gleysols and Gleyed Ferro-Humic Podzols occur in localities with shorter periods of saturation. The presence of eolian and fluviolacustrine veneers containing primary minerals promotes the development of iron, aluminum, and humus enriched B and podzolic B horizons (usually Bhf and podzolic Bhf). Soils with such horizons are most common in western Banff and southwestern Jasper. Favorable moisture, nutrient, and vegetation conditions have resulted in the accumulation of varying thicknesses of fen peat on most wet segment soils. Terric Mesisols occur where the peat is >40 cm thick. Other organic soils with subdominant humic or fibric layers and Humic Gleysols occur occasionally.

A pedon illustrating Terric Mesisols of wet segments of CV1 is described in Table 159. The sample site is shown in Plate 100. This pedon is developed in organic material, containing two thin layers of Eolian material B, overlying Till A. A pedon illustrating Rego Gleysols of CV1 wet segments is described in Table 160. This pedon is developed in organic material, containing one relatively thick layer of Eolian material B, overlying Till B. A low amount of calcium carbonate has been infused into these profiles by seepage. The upward increase in lime content in the Terric Mesisol profile suggests that the site is affected by groundwater discharge.

Eluviated Eutric and Dystric Brunisols best represent soils of CV1 dry segments. Eluviated Eutric Brunisols occur on Till C, Eluviated Dystric Brunisols on Till A or Till B. Orthic Eutric and Dystric Brunisols are important accessory soils occurring where eluvial (Ae) horizons are weakly developed or absent. These soils are most abundant where Eolian material B veneers are absent or surface erosion has recently occurred. Regosolic soils occur on severely eroded localities. Small amounts of Luvisolic soils occur on Till C.

Vegetation

Vegetation of the CV1 Ecosite is distributed in a pattern governed by drainage and seepage conditions. Wet segment vegetation is complex and is best represented by a secondary pattern in which the spruce/Labrador tea/brown moss (O11) and Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) v.t.s are dominant, and the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s are subdominant. The O11 v.t. is most extensive at low elevations (1350-1750 m). The O14 v.t. favors high elevations and steeper slopes and is more abundant in Banff. Few Organic soils occur under O14. The S1 and S3 v.t.s. occur as small patches usually confined to gently sloping benches and depressions within CV1 tracts. On a few CV1 tracts, S1 and S3

are dominant or codominant in relation to the wet open forest vegetation. These tracts (e.g. Snake Indian River valley in the Willow Creek area in Jasper, east end of Shadow Lake in Banff) occur on valley floor benchlands and have, like the Baker Creek (BK) Ecosection, a more pronounced hummocky and ridged relief than normal. Wet depressional segments of these tracts commonly have thin fluvial deposits.

Black spruce-lodgepole pine/willow/sedge (C8) and Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6) are important accessory v.t.s. The C8 v.t. occurs occasionally at low elevations on northerly aspects throughout Jasper. The C8 v.t. is usually abundant to the point of dominance or codominance on a few CV1 tracts in the lower Maligne River valley and the Athabasca River valley below Mt. Fryatt. The O6 v.t. is common on fluvial modified localities with gentle slopes throughout both parks. Intergrades of the above v.t.s, Engelmann spruce-subalpine fir/valerian-fleabane (O9), water sedge-beaked sedge (H11), and other moist to wet shrubby v.t.s occur in small amounts. Modification of the CV1 vegetation by recent fires has occurred in some areas (e.g. Siffleur River valley in Banff). On some of these CV1B tracts, lodgepole pine has replaced spruce in the open forest vegetation.

A stand illustrating O14 of CV1 wet segments is described in Table 161. This stand is located about 50 m northwest of the pedon sample site described in Table 159 and is shown in the background of Plate 100.

A variety of Lower Subalpine spruce and pine forest v.t.s occur on the dry segments of CV1. Distribution is related to fire histories. Being dominantly wet, CV1 is not as frequently or severely affected by fire as other, often adjacent, Lower Subalpine Ecosites. Consequently, spruce forest, usually Engelmann spruce-subalpine fir/feathermoss (C13) correlating to valley floor and lower slope positions, most often dominates dry segments. Occasionlly, Engelmann spruce-subalpine fir/false azalea (C14) is common on relatively steep slopes of mid to lower valley walls. Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) occur sporadically. In areas where fire occurred, lodgepole pine forest, best represented by the cool, moist lodgepole pine/false azalea/grouseberry (C20) and lodgepole pine/Labrador tea (C29) v.t.s, dominates dry segments. Lodgepole pine/feathermoss (C11), lodgepole pine/buffaloberry/grouseberry (C18), and lodgepole pine/buffaloberry/twinflower (C19) are also common in some areas. Modification of these spruce and pine v.t.s by recent fires has occurred in some areas (CV1B tracts).

Discussion

The CV1 Ecosite is broad in concept and encompasses all dominantly wet terrain occurring on morainal landforms in the Lower Subalpine. It encompasses a compound landscape pattern consisting of poorly to very

poorly drained, seepage affected segments and randomly to orderly distributed, well to moderately well drained, dry segments that are not significantly affected by seepage. The proportion of dry segments on CV1 commonly ranges from 5 to 30%. Wet segments are much larger versions of the wet depressional segments contained in the Baker Creek (BK) and Cavell 1 (CA1) Ecosites. In a few cases, CV1 wet segments resemble the Hector 1 and 4 (HC1, HC4) Ecosites. Dry segments resemble the Bryant (BY), Panorama Ridge 1, 2, 3, or 6 (PR1, PR2, PR3, PR6), Cavell 2 or 4 (CA2, CA4), or Moraine Lake 1 or 2 (ML1, ML2) Ecosites. Map presentation of CV1 tracts at scales larger than 1:50,000 is invalid because the wet and dry segments would become mappable as separate Ecosites. In terms of landscape pattern, CV1 resembles the Merlin Castle 1 (MC1) Ecosite. The MC1 Ecosite however, occurs on calcareous, fine textured glaciolacustrine veneers and blankets overlying glacial landforms and is generally restricted to the lower portions of valley floor benchlands with gentle slopes adjacent to river channels. Wetness on MC1 is primarily attributed to surface accumulations of water on slowly pervious soils rather than groundwater discharge and seepage in CV1. The MC1 Ecosite has significantly less Organic soils and slightly different vegetation cover. Sphinx 2 (SX2) is the Upper Subalpine equivalent of CV1 but is dominantly wet, usually lacking a significant proportion of dry areas. There is no Montane counterpart of CV1.

DV - DEVONA ECOSECTION

The Devona (DV) Ecosection encompasses a ridged (dune) landform comprised of calcareous, medium textured eolian material (Eolian material A) occurring in the Montane Ecoregion. Regosolic soils associated with moist white spruce forest and shrubby grassland typify DV. The DV Ecosection is only mapped in Jasper and occurs in the center of the valley floor of the Athabasca River, mainly adjacent to Jasper Lake and northeast to Jasper's East Gate.

Two Ecosites (DV1, DV2) are recognized in the DV Ecosection and are separated primarily on vegetational differences. Table 162 outlines the general features of DV. Fig. 38 shows, schematically, the DV1 Ecosite on the landscape.

DV1 - DEVONA 1 ECOSITE

Ecosite Concept

The Montane Ecosite, DV1, encompasses a ridged (dune) landform comprised of calcareous, medium textured eolian material (Eolian material A). Soils are dominantly Orthic Regosols. Vegetation is characterized by the creeping juniper-northern wheatgrass-sedge (L6) v.t.

Geomorphology

The DV1 Ecosite encompasses ridged, elongate (dune) landforms comprised of calcareous, medium textured eolian material (Eolian material A). The dunes are postglacial deposits derived from the shores of Jasper Lake and the Athabasca River floodplain at low water periods and owe their existence to periodic strong winds which are funneled down the Athabasca River valley (Plate 101). The dunes are up to 25 m deep between Jasper and Talbot Lakes where the majority of DV1 is mapped, but become considerably thinner north and east from Jasper Lake. Actively blowing materials and occasional blowouts on the windward side of the dunes affect less than 10% of DV1. Topographically, DV1 dislays complex slopes commonly ranging from 5 to 30%.

Soils

The DV1 Ecosite is dominated by rapidly drained, extremely calcareous Orthic Regosols that are mainly located immediately east of Jasper Lake where some active wind erosion and deposition still takes place. These soils are free of coarse fragments and vary in texture from very fine sandy loam near source areas adjacent to Jasper Lake, gradually changing to silt loam on landforms in the downwind easterly direction from the source. A pedon illustrating Orthic Regosols of DV1 is described in Table 163.

Vegetation

The DV1 Ecosite is dominated by the creeping juniper-northern wheatgrass-sedge (L6) v.t. which occurs on the drier, exposed portions of these dunes. The moister depressions between the dunes support white spruce thickets, an important associate of the L6 v.t.

Table 162 General features of the Devona (DV) Ecosites.

Ecosite	Landform	Soils	Vegetation
DV1	Eolian material A; ridged	Regosol	shrubby grassland
DV2	Eolian material A; ridged	Regosol	moist white spruce forest

Junegrass-pasture sage-wild blue flax (H6) occurs as an accessory v.t. on DV1. The L6 and H6 v.t.s. have been important in the stabilization of these dunes. *Stipa comata* commonly occurs on DV1 but is rare elsewhere in Banff and Jasper. Unvegetated localities occur where wind erosion is active, producing blowouts. These are commonly found on southerly aspects close to the source material. A plot illustrating the L6 v.t. of DV1 is described in Table 164. Plate 102 shows the vegetation and landscape of DV1. Plate 103 shows a blowout area on DV1 near the north end of Jasper Lake.

Discussion

The DV1 Ecosite may resemble the Talbot 2 (TA2) Ecosite where they both support the H6 v.t. The DV1 Ecosite is differentiated by having much deeper deposits, and is separated from DV2 primarily on vegetational differences as outlined in Table 162. DV1 is mapped only in Jasper.

DV2 - DEVONA 2 ECOSITE

Ecosite Concept

The Montane Ecosite, DV2, encompasses ridged, elongate (dune) landforms comprised of calcareous, medium textured eolian material (Eolian material A). Soils are dominantly Orthic and Cumulic Regosols. Vegetation is dominated by the white spruce/prickly rose/fern moss (C27) v.t. Tracts of DV2 occur on both sides of the Athabasca River valley between the north end of Jasper Lake and Jasper's East Gate.

Geomorphology

The DV2 Ecosite encompasses ridged, elongate (dune) landforms comprised of calcareous, medium textured eolian material (Eolian material A). These dunes occur farther from the source and aggrade at a lesser rate than DV1. Topographically, the dunes of DV2 are not as well developed as those of DV1. The DV2 Ecosite displays complex slopes commonly ranging from 5 to 15% and reflects variation in soil and vegetation that indicate periods of stability mixed with periods of depositional activity.

Soils

The DV2 Ecosite is dominated by Orthic and Cumulic Regosols. These well to rapidly drained soils are extremely calcareous, free of coarse fragments and vary in texture from very fine sandy loam to silt loam. They are still actively aggrading though at a slower rate than DV1. This slower aggradation of loessial materials on DV2 is reflected by Cumulic Regosols with buried Ahk horizons which developed via a process of physical mixing and accretion (Dumanski and Pawluk 1971). A pedon illustrating Cumulic Regosols of DV2 is described in Table 165.

Vegetation

The DV2 Ecosite is dominated by the white spruce/prickly rose/fern moss (C27) v.t. The calciphile *Thuidium abietinum* is the predominant moss in the understory of C27 and reflects the presence of carbonates at the surface. Creeping juniper-northern wheatgrass-sedge (L6) occurs as an accessory v.t. and usually occurs on more open exposed localities within DV2 tracts. A stand illustrating the C27 v.t. of DV2 is described in Table 166 and shown in Plate 28. This stand represents the vegetation near the pedon sample site described above in Table 165.

Discussion

In terms of vegetation cover, soils, and surficial deposits, the DV2 Ecosite most resembles the Talbot 3 (TA3) Ecosite. However, DV2 has much deeper deposits than TA3. The surface expression of TA3 reflects underlying genetic material.

The DV2 Ecosite is separated from DV1 primarily on vegetation differences as outlined in Table 162. DV2 is mapped only in Jasper; however, Rutter (1972) describes a small area of sand dunes three kilometers northeast of Banff townsite. These dunes are small in areal extent and are part of a tract mapped as NY3 with a 5c slope.

EF - EIFFEL ECOSECTION

The Eiffel Ecosection encompasses morainal landforms comprised of noncalcareous, coarse textured till (Till A) in the Alpine Ecoregion of Banff and Jasper (Plate 104). It occurs in the Main Ranges primarily on valley walls and shoulders, cirque basins, and cols in areas that are geologically dominated by Cambrian Gog Group quartzites.

Table 167 General features of the Eiffel 1 (EF1) Ecosite.

Ecosite	Landform	Soils	Vegetation
EF1	Till A: blanket, veneer	Dystric Brunisol, Sombric Brunisol, Ferro-Humic Podzol	heath tundra

Dystric and Sombric Brunisols and Podzols characterize the soil component of EF. These well drained, deeply weathered, well developed soils reflect the acidic, coarse textured parent material, humus accumulation in upper sola and the presence of altered, medium textured eolian (Eolian material B) veneers in cool, moist conditions. The vegetation component is dominated by heath tundra and reflects stable landforms in the moist, cool Alpine environment of the Main Ranges. Table 167 summarizes the characteristics of the one Eiffel Ecosite (EF1). Fig. 43 shows, schematically, the position of EF1 in relation to the Larch Valley (LV) and Moraine Lake (ML) Ecosites.

EF1 - EIFFEL 1 ECOSITE

Ecosite Concept

The Alpine Ecosite, EF1, occurs on morainal blankets and veneers consisting of noncalcareous, coarse textured till (Till A) overlying inclined, hummocky, and ridged bedrock. Soils of the EF1 Ecosite, namely Orthic Dystric Brunisols, Eluviated Dystric Brunisols, Orthic Sombric Brunisols, and Orthic Ferro-Humic Podzols, are well developed, deeply weathered, and well drained. Their development reflects acidic, coarse textured parent material, humus accumulation in upper sola, and the presence of altered, medium textured eolian material (Eolian material B) veneers. The vegetation component is dominated by heather-everlasting (L5) and reflects stable landforms in the cool, moist Alpine environment of the Main Ranges.

Geomorphology

The EF1 Ecosite is typified by morainal blankets and veneers overlying inclined, hummocky, or ridged bedrock. These moraines consist of noncalcareous, coarse textured till (Till A). The low lime phase of Till A rarely occurs. Veneers of altered, medium textured eolian material (Eolian material B) occur extensively on EF1 tracts of western Banff and southwestern Jasper, sporadically elsewhere. Colluvium derived from till and fractured bedrock is found occasionally on the steepest portions of the landscape.

Topographically, EF1 is typified by inclined slopes on valley walls and hummocky or ridged surfaces on valley shoulders, cirque basins, and cols. Bedrock control of surface expression is characteristic. Failed slopes (EF1F) occur, including old rock glaciers, and usually have hummocky surfaces that do not necessarily reflect underlying bedrock surfaces. Slopes commonly range from 5 to 45%. Morainal veneers dominate on EF1X tracts. Bedrock escarpments occur sporadically but are abundant on EF1+R tracts. Patches of colluvial blankets and veneers occur occasionally on the steepest terrain, particularly below bedrock escarpments. The EF1 Ecosite surfaces are often more stony than surfaces on any other morainal Ecosite (Plate 104).

Soils

Orthic Dystric Brunisols, Eluviated Dystric Brunisols, Orthic Sombric Brunisols, and Orthic Ferro-Humic Podzols characterize the soils component of EF1. These well drained soils have thick, well developed sola that reflect the acidity and highly pervious coarse textures of the till parent material. Under the Alpine conditions, humus incorporation into upper sola is significant and the effects of eluviation are often masked, particularly where altered, medium textured eolian material (Eolian material B) is present. Thus, EF1 soils have varying thicknesses of Ah and/or Ahe horizons. Where Eolian material B veneers are very thin or absent, Ahe and Ae horizons are more likely to develop. Where these eolian veneers are present, the soils often have Bhf or podzolic Bhf horizons above, and Bm horizons below the parent material disconformity. Weak cementation (duric tendencies) in lower Bm and BC horizons may occur. Soils with Bf and podzolic Bf horizons, Eluviated Sombric Brunisols, and Sombric Ferro-Humic Podzols also occur occasionally. Lithic soil phases are associated with the morainal veneers. These dominate on EF1X tracts. Turbic phases, produced primarily by solifluction on steep slopes, occur occasionally but are less abundant than on the Molar Pass 1 (MP1) and Jonas 1 (JN1) Ecosites. Seeps with wet soils occur occasionally in depressional localities.

A pedon illustrating Orthic Ferro-Humic Podzols of EF1 is described in Table 168 and shown in Color Plate 16. The upper solum is developed in a mixture of Eolian material B and Till A.

Vegetation

The vegetation of EF1 is dominated by the heather-everlasting (L5) v.t. Accessory v.t.s are mountain avens-snow willow-moss campion (H1) and white mountain heather-mountain

Discussion

In terms of physiographic position, landform surface expression, and vegetation cover, EF1 resembles the Molar Pass 1 (MP1) and Jonas 1 (JN1) Ecosite. The MP1 Ecosite however, occurs on morainal landforms consisting of calcareous, medium textured till (Till C); JN1 occurs on noncalcareous, medium textured till (Till B). The MP1 Ecosite has Eutric and Melanic Brunisols, and Regosolic soils under mountain avens-snow willow-moss campion (H1) and heather-everlasting (L5) vegetation. Soils of the JN1 Ecosite are similar to EF1 soils but are distributed in a different pattern. Vegetation of JN1 includes significant amounts of H1 in addition to L5. The Larch Valley 2 (LV2) Ecosite is the Upper Subalpine counterpart of EF1.

EG - EGYPT ECOSECTION

The Egypt Ecosection encompasses morainal landforms comprised of noncalcareous, medium textured till (Till B) in the Upper Subalpine portion of the Subalpine Ecoregion in Banff and Jasper. The EG Ecosection occurs most extensively in the Main Ranges in association with the Miette Group. It also occurs in the Front Ranges in association with noncalcareous Mesozoic strata. Valley walls, floors, and shoulders, cirque basins, and cols are common physiographic positions in which EG occurs.

The dominant soils, Dystric Brunisols, are moderately developed and reflect the noncalcareous, medium textured parent material and cool, moist Upper Subalpine vegetation. Two groups of coniferous closed and open forest, a pattern of tundra plus coniferous open forest, and a dry > wet landscape pattern differentiate the four Egypt (EG) Ecosites (Table 170). Fig. 39 shows, schematically, the physiographic positions of the Egypt Ecosites

Table 170 General features of the Egypt (EG) Ecosites.

Ecosite	Landform	Soils	Vegetation

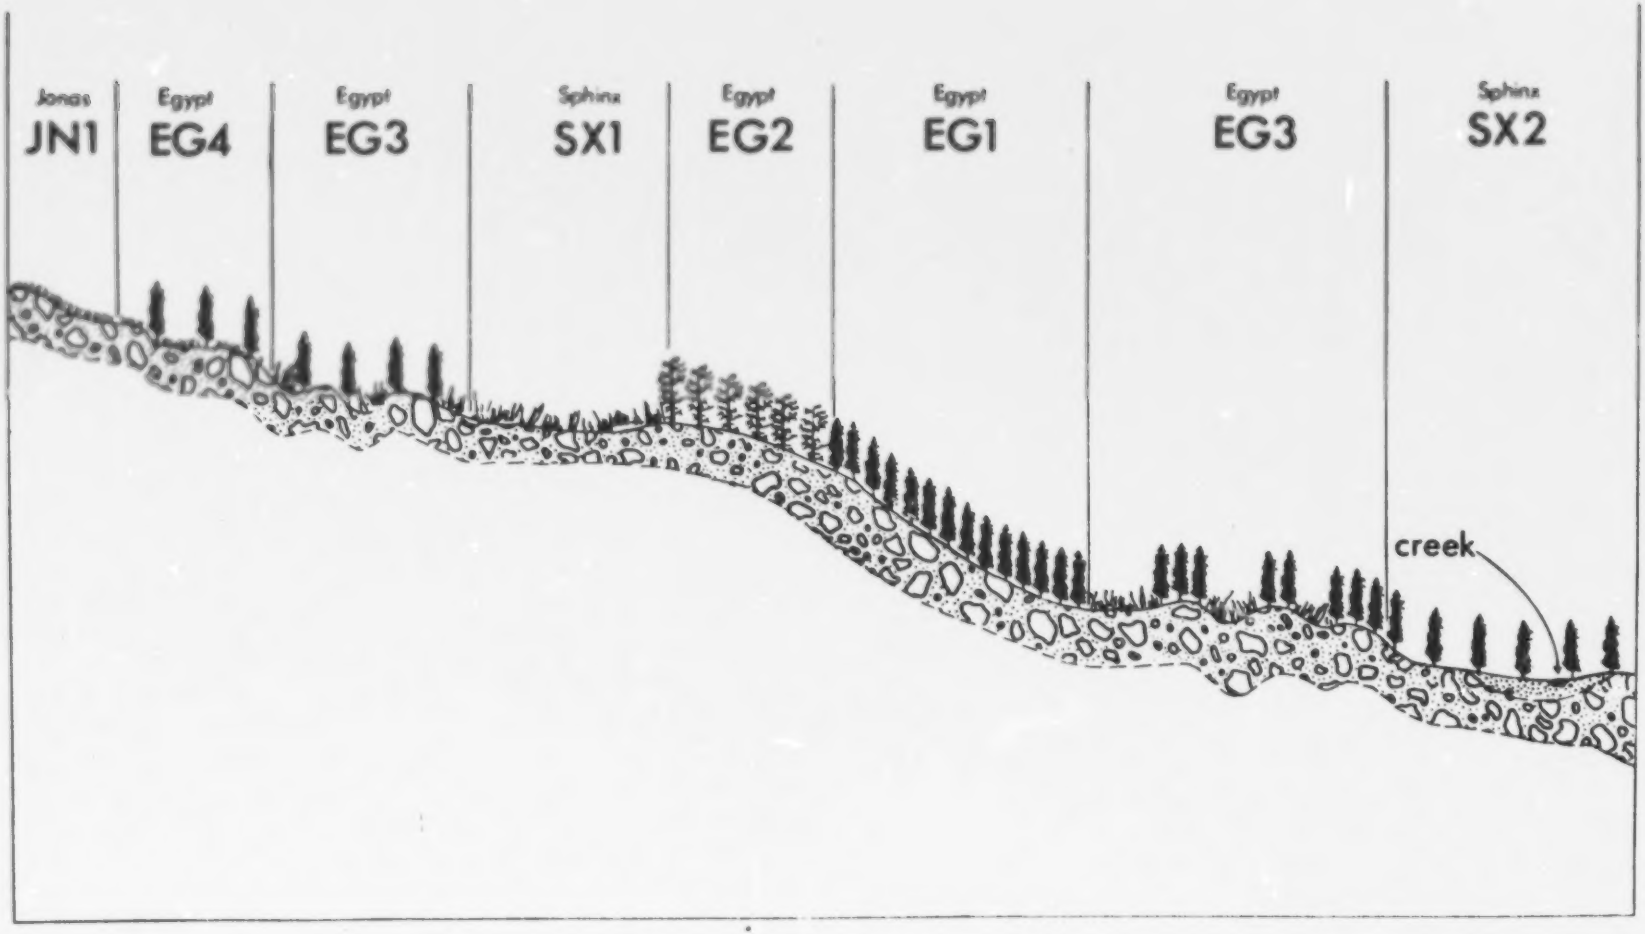
Figure 39 Landscape schematic showing the relationship of the Egypt (EG) Ecosites to other Ecosites.



and their relationship to a few other Upper Subalpine and Alpine Ecosites occurring on noncalcareous, medium textured till.

EG - EGYPT 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EG1, occurs on morainal blankets consisting of noncalcareous, medium textured till (Till B) overlying inclined bedrock on valley walls. The soils normally occur in a pattern reflecting degree of eluvial (Ae) horizon development. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant. Vegetation cover is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), and Engelmann spruce-subalpine fir/heather (O10) v.t.s. C15 and O10 are most abundant but some EG1 tracts are dominated by C21 or C21 plus O10.

Geomorphology

The EG1 Ecosite is typified by morainal blankets overlying inclined bedrock. These moraines consist of noncalcareous, medium textured till (Till B). Surface veneers of altered, medium textured eolian material (Eolian material B) occur extensively on EG1 tracts of western Banff and southwestern Jasper, sporadically elsewhere. Colluvium derived from till and fractured bedrock is found occasionally on the steepest portions of the landscape. A medium textured variant of noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A), derived from slates and shales, may occur occasionally on lower valley wall slopes.

Topographically, EG1 displays long, linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes commonly range from 15 to 70%. Occasionally, linear slopes dissected by gullies occur but much less frequently than on the Peyto Lake 1 (PL1) and Larch Valley 3 (LV3) Ecosites occurring on linear slopes of calcareous, medium textured till (Till C) and noncalcareous, coarse textured till (Till A) respectively. Patches of colluvial blankets and veneers occur occasionally on the steepest terrain, especially below bedrock escarpments. Tracts of EG1 situated along valley floors, at valley confluences, on valley shoulders, in cirque basins and cols, and on failed slopes often display morainal landforms with irregular surfaces and complex topography (5-45% slopes). These landforms include morainal blankets and veneers overlying ridged and hummocky bedrock and the relatively deep till of hummocky moraines. Morainal veneers also occur on linear, inclined slopes and are dominant on tracts mapped as EG1X. Bedrock outcrops occur occasionally but are particularly common on EG1+R tracts.

Soils

The soils of the EG1 Ecosite are distributed in a pattern that reflects degree of eluvial (Ae) horizon develoment. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant. These well to moderately well drained soils have B horizons that range from comparatively well developed Bm and Bf horizons, associated with altered, medium textured eolian material (Eolian material B) above the parent material disconformity, to moderately developed Bm horizons in the till. Genetically related Orthic Humo-Ferric Podzols with >10 cm of Bf horizon above the parent material disconformity are important accessory soils. These are most abundant on EG1 tracts with extensive Eolian material B veneers. Soils with Bhf and podzolic Bhf horizons occur in minor amounts. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly developed in the absence of Eolian material B. In some localities, recent surface disturbances such as wind throw of trees, avalanching, sheet erosion, and soil creep have inhibited or destroyed Ae horizon development. Many of the EG1 Ecosite soils have, in lower sola and upper C horizons, clay films that are thought to be formed by pressure (e.g. freeze-thaw) rather than clay illuviation. Small amounts of wet soils occur in seeps of depressional localities and Regosolic soils on steep, colluviating portions of the landscape. Lithic soil phases occur sporadically on EG1 but dominate on EG1X tracts.

A pedon illustrating Orthic Dystric Brunisols of EG1 is described in Table 171. Although located within the area of extensive Eolian material B veneers, erosion on this site has removed most of the eolian material. Soil materials on EG1 are generally deeper than this lithic phase pedon. Clay film development as in the lower solum of this pedon is common in soils developed in noncalcareous, medium textured till.

Vegetation

The EG1 Ecosite is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), and Engelmann spruce-subalpine fir/heather (O10) v.t.s, with C15 and O10 being most abundant. The C15 v.t. is most abundant above the boundary between Lower and Upper Subalpine. The O10 v.t. occurs above C15 and is most extensive on northerly aspects. The C21 v.t. replaces C15 throughout northern Jasper (north of the range of *Vaccinium scoparium*) and on many EG1 tracts near the Continental Divide. The accessory v.t., Engelmann spruce-subalpine fir/heather/feathermoss (C34), often occurs at

higher elevations than C15 or C21 and below O10. Notable v.t.s in minor amounts are subalpine larch-subalpine fir/grouseberry-everlasting (C23) in southern Banff; Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) and Engelmann spruce/hairy wild rye (C33) on southerly aspects, and Engelmann spruce-subalpine fir/rock willow/white mountain heather (C24) on northerly aspects on EG1 tracts associated with Mesozoic strata in eastern Banff and Jasper. Various moist to wet Upper Subalpine v.t.s occur on seeps in depressional localities. Snow avalanche v.t.s such as subalpine fir-willow (S2) occur on avalanched portions of the landscape. Fire affected vegetation in which spruce is regenerating occurs in some areas, e.g. between the Panther and Red Deer River valleys east of the Bare Mountains in Banff. Lodgepole pine/buffaloberry/ grouseberry (C18) sometimes occurs in or adjacent to burned areas.

A stand illustrating the C15 v.t. of EG1 is described in Table 172. This stand is located about 100 m from the pedon sample site described above (Table 171).

Discussion

The EG1 Ecosite is the most extensive of the Egypt Ecosites. In terms of physiographic position, landform surface expression, and vegetation, EG1 resembles the Peyto Lake 1 (PL1) and Larch Valley 3 (LV3) Ecosites. However, PL1 differs because it occurs on morainal landforms consisting of calcareous, medium textured till (Till C); LV3 because it occurs on noncalcareous, coarse textured till (Till A). Also, PL1 is dominated by Eutric Brunisols and LV3 is characterized by Dystric Brunisols with thicker sola and Ae horizons than EG1 soils. The EG1 Ecosite is differentiated from other Egypt Ecosites by vegetation differences and amount of wet, seepage affected landscape as outlined in Table 170. The Cavell 2 (CA2) Ecosite is the Lower Subalpine counterpart of EG1.

EG2 - EGYPT 2 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EG2, occurs on morainal blankets consisting of noncalcareous, medium textured till (Till B) overlying inclined, hummocky, and ridged bedrock. Veneers of altered, medium textured eolian material (Eolian material B) occur extensively and significantly affect soil development. Consequently, EG2 exhibits a soil pattern in which Eluviated Dystric Brunisols are dominant and Orthic Humo-Ferric Podzols are subdominant. Vegetation is dominated by the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. The EG2 Ecosite is the least extensive of the Egypt Ecosites and is found only in Banff south of a line joining Hector Lake, Pipestone Pass, and the Panther River.

Geomorphology

The EG2 Ecosite is typified by morainal blankets overlying inclined, hummocky, or ridged bedrock. These moraines consist of noncalcareous, medium textured till (Till B). The low lime phase occurs rarely. Veneers of altered, medium textured eolian material (Eolian material B) occur extensively. Colluvium derived from till or fractured bedrock occurs rarely.

Topographically, EG2 displays linear, inclined slopes on valley walls or hummocky and ridged surfaces on valley shoulders (Plate 105), cirque basins, and cols. These surface expressions usually reflect underlying bedrock surfaces. Slopes commonly range from 5 to 45%. Morainal veneers and bedrock outcrops occur occasionally. On EG2X tracts morainal veneers dominate and bedrock escarpments are more common than normal for EG2. Deep till deposits, usually with a hummocky surface form, occur occasionally on cirque floors and on failed slopes.

Soils

Eluviated Dystric Brunisols are the dominant soils of the EG2 Ecosite, Orthic Humo-Ferric Podzols the subdominant soils. These well to moderately well drained soils reflect the presence of nearly continuous veneers of altered, medium textured eolian material (Eolian material B) in that they have comparatively well developed Bm, Bf, or podzolic Bf horizons above the parent material disconformity and moderately developed Bm horizons below. The accessory soils, Orthic Dystric Brunisols, occur locally where Eolian material B veneers are absent, where recent surface disturbances have inhibited or destroyed Ae horizon development, or where significant humus incorporation masks the effects of eluviation. Most EG2 soils show, in their upper sola, humic enrichment attributable to the near Alpine environment with larch forest. Consequently, soils with Bhf and podzolic Bhf horizons occur occasionally. Many EG2 soils have, in lower sola and upper C horizons, clay films that are thought to be formed by pressure (e.g. freeze-thaw) rather than illuviation. Wet soils associated with seeps in de-

pressional sites, occur in minor amounts. Lithic soil phases occur sporadically on EG2, being most abundant on hummock and ridge crests. On EG2X tracts, lithic phases are dominant.

A pedon illustrating Orthic Humo-Ferric Podzols of EG2 is described in Table 173. Note the morphological evidence of humus incorporation as shown by the thin Ah horizon at the mineral surface in this pedon.

Vegetation

The EG2 Ecosite is dominated by the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. An open tree canopy variant of C23 occurs on exposed sites and along the upper elevational boundaries of EG2 tracts. Stunted variants or other avalanche v.t.s such as subalpine fir-willow (S2) occur on avalanched portions of the landscape. Because of map scale limitations, many EG2 tracts have minor amounts of Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), or Engelmann spruce-subalpine fir/heather (O10) along lower elevational boundaries and patches of heather-everlasting (L5) along upper boundaries. Various moist to wet Upper Subalpine v.t.s, as well as C23 are associated with seeps in depressional localities. A stand representing vegetation of the pedon sample site described above (Table 173) and illustrating the open canopy variant of C23 on EG2 is presented in Table 174 and Plate 106.

Discussion

The EG2 Ecosite is the least extensive of the Egypt Ecosites. Its distribution is governed by the geographic range of subalpine larch-subalpine fir/grouseberry-everlasting (C23) on noncalcareous, medium textured till (Till B). In terms of physiographic position, landform surface expression, and vegetation, EG2 resembles the Peyto Lake 3 (PL3) and Larch Valley 3 (LV3) Ecosites. However, PL3 occurs on morainal landforms consisting of calcareous, medium textured till (Till C); LV3 occurs on noncalcareous, coarse textured till (Till A). The PL3 Ecosite exhibits a Eutric Brunisol > Podzol soil pattern. The LV3, like EG2, has a Dystric Brunisol > Podzol soil pattern but its soils are more deeply weathered reflecting coarse parent material. The EG2 Ecosite is differentiated from other Egypt Ecosites by vegetation differences and amount of wet, seepage affected landscape as outlined in Table 170.

EG3 - EGYPT 3 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EG3, occurs on morainal blankets and veneers consisting of noncalcareous, medium textured till (Till B) overlying hummocky and ridged bedrock that form a compound landscape comprised of about 70% dry (well to moderately well drained, mesic) upland segments and 30% wet (imperfectly to poorly drained, subhygric to subhydric), seepage affected depressions between ridges and hummocks. Upland soils occur in a pattern reflecting degree of eluvial (Ae) horizon development. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant. Vegetation of upland segments is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15) and Engelmann spruce-subalpine fir/heather (O10) v.t.s except in southern Banff where the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. commonly occurs. A complex set of pedogenically related soils, represented by the Orthic Gleysol, Rego Gleysol, Gleyed Ferro-Humic Podzol, and Gleyed Dystric Brunisol subgroups, occur on wetland segments, usually under the Engelmann spruce-subalpine fir/valerian-fleabane (O9) and fleabane-valerian (H16) v.t.s.

Geomorphology

The EG3 Ecosite is typified by morainal blankets and veneers overlying hummocky and ridged bedrock. These moraines consist of noncalcareous, medium textured till (Till B).

In a few areas, e.g. Redearth Pass in Banff, EG3 tracts include morainal landforms consisting of noncalcareous, coarse textured till (Till A). Surface veneers of altered, medium textured eolian material (Eolian material B) occur extensively on EG3 tracts of western Banff and southwestern Jasper, sporadically elsewhere. Redeposition of this eolian material in thin, altered, fine, stratified fluviolacustrine (Fluviolacustrine material A) veneers has occurred on some depressions. Genetic materials of depressional segments include the till or noncalcareous, coarse, stratified fluvial material (Fluvial material A) existing as level floodplains or veneers and blankets overlying till. These materials may be overlain by the thin fluviolacustrine and eolian veneers. Occasionally, horizontal fens comprised of shallow, moderately decomposed, fen peat may occur on ponded portions of the depressions. Noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) and colluvium occur rarely on EG3 tracts.

Topographically, EG3 displays a series of subparallel ridges or irregularly distributed knolls (hummocks) separated by gently sloping depressions. The EG3 Ecosite is usually found on valley floors, valley shoulders, cirque basins, and cols. Slopes commonly range from 5 to 45% overall although slopes of <5% are common on depressional segments. Depressions may be level with abrupt borders to upland segments or concave and bowl shaped with subtle margins. Morainal veneers dominate on EG3X tracts. Bedrock outcrops are most common on EG3+R tracts. A few EG3 tracts have linear slopes on lower valley walls, straddling long narrow wetlands along the valley floor. Deep till deposits, usually with a hummocky surface form, occur occasionally on failed slopes and on valley and cirque floors.

Soils

Soils of the EG3 Ecosite are distributed in a pattern governed by drainage conditions. Well to moderately well drained upland segments exhibit a secondary soil pattern reflecting degree of eluvial (Ae) horizon development. Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols subdominant in a pattern most often resembling EG1 soil distribution. These soils have B horizons that range from moderately developed Bm horizons at the till surface to the comparatively advanced Bm and Bf horizons associated with altered, medium textured eolian material (Eolian material B). Genetically related Orthic Humo-Ferric Podzols with podzolic Bf horizons above the parent material disconformity are important accessory soils. These are most abundant on EG3 tracts with extensive Eolian material B veneers. Soils with Bhf and podzolic Bhf horizons occur in minor amounts. Eluvial (Ae) horizons are discontinuous across the landscape and are often only weakly developed in the absence of Eolian material B. In some localities, recent surface disturbances such as wind throw of trees, avalanching, sheet erosion, and soil creep have inhibited or destroyed Ae horizon development. Masking of the eluviation process occurs on soils with humus enriched surface horizons under subalpine larch-subalpine fir/grouseberry-everlasting (C23) or heather-everlasting (L5) vegetation. Consequently, on several EG3 tracts soils of upland segments resemble EG2 soils or EG4 soils. Orthic Sombric Brunisols occur in minor amounts, particularly under L5. Many EG3 upland soils display, in lower sola and upper C horizons, clay films thought to be formed by pressure (e.g. freeze - thaw). Lithic soil phases are associated with morainal veneers and dominate on EG3X tracts. The pedons described in Tables 171, 173, and 175 illustrate soils of the upland segment of EG3.

A variety of pedogenically related and geomorphically modified soils occur on the imperfectly to poorly drained, depressional segments of the EG3 Ecosite. These are best represented by the Orthic Gleysol, Rego Gleysol, Gleyed Ferro-Humic Podzol, and Gleyed Dystric Brunisol Subgroups. Strength of gleying, reflecting degree of movement and aeration of seepage waters, is variable. The presence of eolian or fluviolacustrine veneers promotes the development of iron, aluminum, and humus enriched B and podzolic B horizons (usually Bhf and podzolic Bhf). Recent and continuing fluvial deposition, long periods of saturation, and severe solifluction or cryoturbation retard or destroy pedogenic horizonation (Rego Gleysols). Turbic phases of other soils also occur. Gleyed Eluviated Dystric Brunisols, various gleyed Regosolics, and Humic Gleysols may be found occasionally. Terric Mesisols occur occasionally on ponded sites. The pedons described in Tables 340, 342, and 344 for the Sphinx (SX) Ecosites illustrate soils common to EG3 depressional segments.

Vegetation

Vegetation of the EG3 Ecosite is distributed in a pattern governed by drainage conditions. The upland segments are dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/heather (O10), and subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t.s. The C15 and O10 v.t.s. are most abundant and resemble EG1 vegetation. Upland segments of several EG3 tracts in southern Banff are dominated by C23, thereby resembling EG2. Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) in northern Jasper and along the Continental Divide, Engelmann spruce-subalpine fir/heather/feathermoss (C34), and at high elevations heather-everlasting (L5) are important accessory v.t.s. Modification by

snow avalanching and fire has occurred in some areas.

A variety of moist to wet Upper Subalpine v.t.s, best represented by Engelmann spruce-subalpine fir/valerian-fleabane (O9) and fleabane-valerian (H16), occur on the seepage affected depressional segments of the EG3 Ecosite. Willow/cinquefoil (S8) is an accessory v.t. and occurs most often on EG3 tracts of eastern Banff and Jasper on till and fluvial materials derived from Mesozoic strata. Occasionally O10 and C23 extend onto depressions from upland localities. Other v.t.s in minor amounts are dwarf birch-shrubby cinquefoil/needlerush (S3), willow/timber oatgrass (S11), Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14), mountain marigold-globeflower (H9), and an Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) variant in recently burned areas.

Discussion

The EG3 Ecosite encompasses a compound landscape pattern consisting of well to moderately well drained upland segments similar to EG1, occasionally to EG2 and EG4, and imperfectly to poorly drained depressional segments similar to the Sphinx (SX) or Num-Ti-Jah 2 (NT2) Ecosites. The proportion of wet depressions on EG3 tracts commonly ranges from 20 to 40%. Map presentation of EG3 tracts at scales larger than 1:50,000 is invalid because these segments would become mappable as separate Ecosites. The EG3 Ecosite most closely resembles the Peyto Lake 5 (PL5) Ecosite. The PL5 Ecosite however, occurs on morainal landforms consisting of calcareous, medium textured till (Till C) and is dominated by Eutric Brunisols on upland segments. The infrequent Upper Subalpine occurrences of a dry > wet pattern on noncalcareous, coarse textured till (Till A) landforms are also mapped as EG3. The Cavell 1 (CA1) Ecosite is the Lower Subalpine counterpart of EG3.

EG4 - EGYPT 4 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EG4, occurs on morainal blankets and veneers consisting of noncalcareous, medium textured till (Till B) overlying inclined, hummocky, and ridged bedrock. A soil pattern relating to the amount of humus accumulation and presence of altered, medium textured eolian (Eolian material B) veneers characterizes EG4. Orthic and Eluviated Dystric Brunisols are dominant; Orthic Sombric Brunisols and Orthic Ferro-Humic Podzols are subdominant. A pattern of heather-everlasting (L5) interspersed with islands of Engelmann spruce-subalpine fir/heather (O10) characterizes the vegetation of this Ecosite. The EG4 Ecosite represents the uppermost part of the Upper Subalpine on noncalcareous, medium textured till and is normally bounded above by Alpine Ecosites and below by Upper Subalpine Ecosites with closed to open forests of Engelmann spruce - subalpine fir or subalpine larch - subalpine fir.

Geomorphology

The EG4 Ecosite is typified by morainal blankets and veneers overlying inclined, hummocky, and ridged bedrock. These moraines consist of noncalcareous, medium textured till (Till B). Surface veneers of altered, medium textured eolian material (Eolian material B) occur extensively on EG4 tracts of western Banff and southwestern Jasper, sporadically elsewhere. Colluvium derived from till or fractured bedrock is found occasionally on the steepest portions of the landscape. Noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) rarely occurs.

Topographically, EG4 displays linear, inclined slopes on valley walls or hummocky and ridged surfaces on valley shoulders, cirque basins, and cols. These surface expressions usually reflect underlying bedrock surfaces. Slopes commonly range from 5 to 70%. Linear slopes are occasionally gullied. Morainal veneers are common and dominate on EG4X tracts. Bedrock outcrops are most common on EG4+R tracts. Patches of colluvium existing as blankets and veneers occur occasionally on the steepest terrain, particularly below bedrock escarpments. Deep till deposits, usually with a hummocky surface form, occur occasionally on failed slopes and cirque floors.

Soils

A soil pattern in which Orthic and Eluviated Dystric Brunisols are dominant and Orthic Sombric Brunisols and Orthic Ferro-Humic Podzols subdominant characterizes the EG4 Ecosite. In the near Alpine environment organic matter accumulation in the upper sola of these soils is significantly greater than on other Egypt Ecosite soils. Thus, the effects of eluviation are often masked and EG4 soils have varying thicknesses of Ah and Ahe horizons. Where altered, medium textured eolian material (Eolian material B) veneers are present, these soils often have advanced Bhf or podzolic Bhf horizons above and moderately developed Bm horizons below the parent material disconformity. Soils with Bf and podzolic Bf horizons occur occasionally. Some EG4 soils display, in lower sola and upper C horizons, clay films thought to be formed by pressure (e.g. freeze-thaw) rather than illuviation. Turbic soil phases produced by cryoturbation and solifluction are common among EG4 soils, particularly on EG4 tracts of eastern Banff and Jasper. Lithic phases

are associated with morainal veneers and dominate on EG4X tracts. Depressional localities with various seepage affected wet soils may constitute up to 20% of EG4 tracts. Regosolic soils occur occasionally on severely soliflucted, cryoturbated, and colluviated sites.

A pedon illustrating Orthic Dystric Brunisols (lithic phase) of EG4 is described in Table 175 and shown in Color Plate 17. Textural characteristics of this pedon's surface horizons suggest that the Eolian material B at this site has been reworked by slowly moving water. Soils of the EG4 Ecosite normally have deeper till and thicker sola than this pedon displays.

Vegetation

The EG4 Ecosite is dominated by a vegetation pattern in which the heather-everlasting (L5) v.t. is more abundant than the Engelmann spruce-subalpine fir/heather (O10) v.t. The O10 v.t. normally exists as discrete patches or islands of trees but includes islands of krummholz on exposed sites or at

the Upper Subalpine - Alpine boundary. Tree islands cover about 50% of the landscape at lowest elevations, 5% at highest elevations. Islands of subalpine larch-subalpine fir/grouseberry-everlasting (C23) often replace O10 on EG4 tracts located in southern Banff. Patches of white mountain heather-mountain avens-snow willow (L4) and mountain avens-snow willow-moss campion (H1) occur occasionally with H1 being restricted to exposed ridge and hummock crests or to severely soliflucted sites on EG4 tracts associated with Mesozoic strata in eastern Banff and Jasper. Seepage affected depressional localities often have moist Upper Subalpine v.t.s such as Engelmann spruce-subalpine fir/valerian-fleabane (09) and fleabane-valerian (H16). Modification by avalanching and fire, although difficult to identify on EG4 vegetation, occurs occasionally. A stand representing vegetation of the pedon sample site described above (Table 175) and illustrating the L5 segment of the EG4 vegetation pattern is described in Table 176.

Table 176 Stand (JE8159) illustrating the heather-everlasting (L5) portion of the v.t. pattern of the EG4 Ecosite.

Discussion

The EG4 Ecosite represents the Upper Subalpine - Alpine ecotone on noncalcareous, medium textured till (Till B). In terms of physiographic position, landform surface expression and vegetation, EG4 resembles the Peyto Lake 4 (PL4) and Larch Valley 2 (LV2) Ecosites. However, PL4 occurs on morainal landforms consisting of calcareous, medium textured till (Till C); LV2 occurs on noncalcareous, coarse textured till (Till A). The PL4 Ecosite has Eutric and Melanic Brunisols. The LV2 Ecosite, like EG4, has Dystric and Sombric Brunisols but its soils are more deeply weathered, reflecting coarse textured parent material. The EG4 Ecosite is differentiated from other Egypt Ecosites by vegetation differences and amount of wet, seepage affected landscape as outlined in Table 170. Jonas 1 (JN1) is the Alpine counterpart of EG4.

EN - ENDLESS CHAIN ECOSECTION

The Endless Chain (EN) Ecosection encompasses steep, usually linear, colluvial landforms comprised of noncalcareous, coarse textured colluvium (Colluvium A) in the Upper Subalpine portion of the Subalpine Ecoregion of Banff and Jasper. It occurs principally in the Main Ranges on or below steep, rocky, valley walls in areas that are geologically dominated by Cambrian Gog Group quartzites.

Deeply weathered Dystric Brunisols are dominant and reflect, in their development, the coarse textured, acidic parent material. Minor morphological irregularities are attributable to past and present colluvial activity. Regosolic soils are, in some cases, subdominant and correlated with localities of most active colluviation. Three Endless Chain Ecosites are differentiated on vegetation differences (Table 177) that reflect type and degree of colluvial activity. Vegetation on EN includes Engelmann spruce - subalpine fir closed and open forest, mixed coniferous open forest, and an avalanche complex of v.t.s. Fig. 40 shows, schematically, the physiographic positions of the EN1, EN2 and EN3 Ecosites.

EN1 - ENDLESS CHAIN 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EN1, encompasses blankets and veneers consisting of noncalcareous, coarse textured colluvium (Colluvium A) overlying inclined bedrock on steep valley walls. The deeply weathered EN1 soils, dominated by Eluviated Dystric Brunisols, suggest by their development that colluviation is slow enough that it is not preventing profile development. Likewise, vegetation is well developed and is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), and Engelmann spruce-subalpine fir/heather (O10) v.t.s. The C15 v.t. is most abundant.

Figure 40 Landscape schematic showing the relationship of the Endless Chain Ecosites (EN1, EN2, and EN3) to other Ecosites.

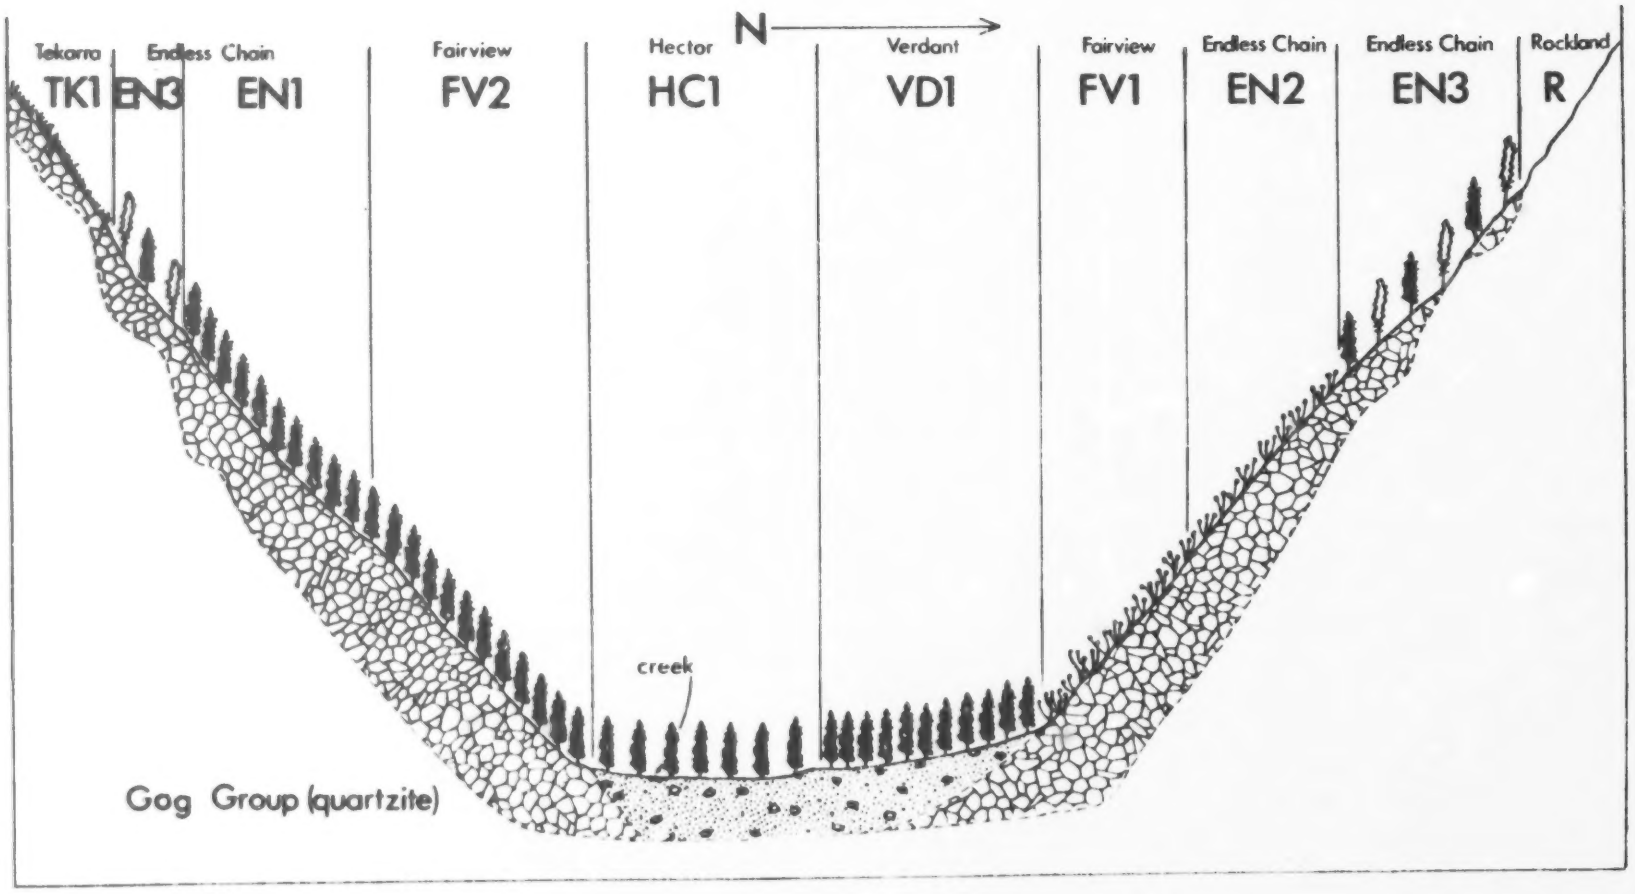

Table 177 General features of the Endless Chain (EN) Ecosites.

Ecosite	Landform	Soils	Vegetation
EN1	Colluvium A; blanket, veneer	Dystric Brunisol	Engelmann spruce-subalpine fir closed and open forests
EN2	Colluvium A; blanket, veneer, , apron	Dystric Brunisol > Regosol	Avalanche Complex 2 > mixed coniferous open forest, Engelmann spruce-subalpine fir open forest
EN3	Colluvium A; blanket, veneer > bedrock; inclined	Dystric Brunisol > Regosol	mixed coniferous open forest > Engelmann spruce-subalpine fir open forest

Geomorphology

The EN1 Ecosite occurs on colluvial blankets and veneers consisting of noncalcareous, coarse textured colluvium (Colluvium A) overlying inclined bedrock on steep valley walls. Underlying bedrock is predominantly Gog Group quartzites although some EN1A tracts, such as one north of Cascade Mountain in Banff, contain material derived from quartz sandstone of the Rocky Mountain Group. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically and are most abundant on EN1 tracts of western Banff and southwestern Jasper. Erosional and colluvial processes have removed or incorporated most evidence of the wind blown accumulation. Till occasionally underlies colluvial material along lower, more gentle slopes of EN1 tracts. Thin fluvial deposits, generally a weakly sorted variant of noncalcareous, coarse, stratified fluvial material (Fluvial material A), occasionally are interbedded with colluvium on avalanched portions of EN1A tracts.

Topographically, EN1 displays long, linear slopes commonly ranging from 45 to 90%. Tracts of EN1 with complex topography exhibit linear colluvial slopes whose continuity is broken by one or more exceptionally steep rock escarpments. Surface form is controlled by deposition and underlying bedrock. The colluvial material is generally shallowest (veneers) at the tops of slopes and deepens downslope. Colluvial aprons occur occasionally along slope bases at major slope breaks. Colluvial veneers dominate EN1X tracts.

Soils

The soil development of the EN1 Ecosite reflects acid, rapidly pervious, parent material and stable geomorphic conditions. Eluviated Dystric Brunisols are dominant. These rapidly to well drained soils have strongly developed B horizons, thick sola, and thick, well developed, eluvial (Ae) horizons. Orthic Dystric Brunisols and Orthic Humo-Ferric Podzols are important accessory soils. Orthic Dystric Brunisols occur on localities where surface disturbances such as avalanching are sufficient to inhibit or destroy Ae horizon development. Orthic Humo-Ferric Podzols are associated with the altered, medium textured eolian (Eolian material B) veneers and have podzolic Bf horizons above the parent material disconformity. Orthic Regosols occur in minor amounts on rubbly and actively colluviating sites.

A pedon illustrating Eluviated Dystric Brunisols of EN1 is described in Table 178 and shown in Color Plate 18. The upper solum is developed in a mixture of Eolian material B and Colluvial material A. The PH characteristics through the profile suggest that these parent materials of the upper solum are young or contained some calcareous particles. The IIBC1 horizon contains clay films, a feature not common to EN1 soils.

Vegetation

Vegetation cover of the EN1 Ecosite indicates stable geomorphic conditions. The Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), and Engelmann spruce-subalpine fir/heather (O10) v.t.s are dominant. Within the elevational range of EN1, C15 is most abundant and extensive at low elevations and on southerly aspects. A few EN1 tracts are dominated by C21 and O10. The C21 v.t. replaces C15 throughout northern Jasper (north of the range of *Vaccinium scoparium*) and on some tracts near the Continental Divide. The O10 v.t. occurs above C15 and C21 and is most extensive on northerly aspects. Subalpine larch—subalpine fir/grouseberry—everlasting (C23) is an important accessory v.t. occurring on several EN1 tracts in southwestern Banff south of Hector Lake and Pipestone Pass. Many tracts mapped as EN1A have up to 50% of their area avalanched and contain avalanche v.t.s. such as subalpine fir-willow (S2) and juniper-willow (L2). A plot representing vegetation of the pedon sample site described above (Table 178) and illustrating C15 on

Discussion

The EN1 Ecosite is the least extensive of the Endless Chain Ecosites and is of limited extent overall. In terms of landform surface expression, physiographic position, and vegetation cover, EN1 resembles the Wildflower 1 (WF1) and Whitehorn 2 (WH2) Ecosites. However, in contrast to the Colluvium A characterizing EN1, WF1 occurs on landforms consisting of calcareous, medium textured colluvium (Colluvium C), and WH2 occurs on noncalcareous, medium textured colluvium (Colluvium B). Also, WF1 has neutral to alkaline Eutric Brunisols and a significant amount of Regosolic soils. The WH2 Ecosite, like EN1, has Dystric Brunisols but in the former both sola and Ae horizons are thinner. The EN2 and EN3 Ecosites are differentiated from EN1 primarily by vegetation differences (Table 177) that reflect varying type and degree of colluvial activity. The Fairview 2 (FV2) Ecosite, where it occurs on landforms of noncalcareous, coarse textured colluvium (Colluvium A), is the Lower Subalpine counterpart to EN1.

EN2 - ENDLESS CHAIN 2 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EN2, encompasses avalanched colluvial landforms comprised of noncalcareous, coarse textured colluvium (Colluvium A). These exist as blankets and veneers overlying inclined bedrock on steep valley walls and as aprons along slope bases at major slope breaks. Snow avalanching is characteristic and governs the distribution of vegetation and, to a lesser extent, soils. Perla and Martinelli (1975) discuss much of the scope of avalanching. A soil pattern in which Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols and Orthic Regosols are subdominant typifies the soil component of EN2. Avalanched segments dominate and are characterized by a heterogeneous complex of v.t.s that include subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (S10), juniper-willow (L2), hairy wild rye-wild strawberry-fireweed (H5), fleabane-valerian (H16) plus intergrades, collectively called Avalanche Complex 2. Forested strips and patches between avalanche tracks and fringing runout zones are subdominant and best represented by the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) and Engelmann spruce-subalpine fir/heather (O10) v.t.s.

Geomorphology

The EN2 Ecosite occurs on blankets, veneers, and aprons comprised of noncalcareous, coarse textured colluvium (Colluvium A). Source bedrock is predominantly Gog Group quartzite, but quartz sandstone occurs occasionally. For example, one EN2 tract near Pipestone Pass warden cabin in Banff contains material derived from the Mount Wilson Formation. More than 50% of EN2 is modified by snow avalanching. Avalanching of such areal extent usually occurs as coalescing unconfined avalanche paths, or as runout zones below the length of a cliff. Gully-like channeled avalanche tracks (chutes) are common as well.

Genetic material stability within EN2 tracts is greatest on portions unaffected by avalanching, but the unconfined avalanche tracks are almost as stable. Together these components make up a majority of the area of most EN2 tracts. Instability is of two kinds. Erosion of unconsolidated material occurs, though infrequently, on steep avalanche starting zones and on walls of channeled tracks. It is usually evidenced by sparsely vegetated patches. Deposition is a more common process and frequently includes material derived from bedrock exposures high on, or above the EN2 tract. Talus also occurs, with its location and extent controlled by the cliffs above. Material carried by avalanching is distributed downslope to gentler runout zones. Colluvial material is modified by intermittent streams below couloirs and on avalanche runout zones. Fluvial deposits, occurring as thin veneers and layers interbedded with colluvium, are most abundant below channeled tracks and couloirs.

This fluvial material is a weakly sorted variant of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and, like the colluvium, is coarse textured with a high content of angular coarse fragments. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically on the subdominant unavalanched segments of the landscape. Rubble without fine earth material for soil development is common on some EN2 tracts, particularly those occurring as aprons below steep rock walls (e.g. colluvial aprons along the bases of Mt. Mahood and Mt. Moren in the upper Miette River valley in Jasper).

Topographically, EN2 displays long, linear, inclined slopes commonly ranging from 45 to 90%. Slopes <45% occur on the lower slopes and toes of colluvial aprons. Surface form is controlled by deposition and underlying bedrock. The colluvial material is generally shallowest (veneers) at the tops of slopes and deepens downslope to form aprons along slope bases at major slope breaks. Colluvial aprons also occur below rock walls. Shallow channels and accompanying levees, constructed by intermittent streams, are often associated with a wide range of gullying on avalanche tracks. Colluvial veneers dominate those tracts mapped as EN2X. Tracts with failed slopes, mapped as EN2F, occur occasionally. These include slopes characterized by failure of the unconsolidated material and partial failure of underlying bedrock.

Soils

Soil distribution and development on the EN2 Ecosite is related to genetic material stability as influenced by avalanching and supplementary processes. A soil pattern, in which Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols and Orthic Regosols are subdominant, characterizes EN2. Eluviated Dystric Brunisols occur where geomorphic activity is least frequent or intense, especially on the forested segments or avalanched segments without cliffs above. Orthic Dystric Brunisols occupy localities where surface modification is weak but eluvial (Ae) horizon development is retarded or has been destroyed. On localities where erosion or deposition is frequent and intense, Orthic Regosols are abundant.

Soils of the EN2 Ecosite are rapidly to well drained and reflect, in their development, the acidic, rapidly pervious, parent material. The Brunisolic soils have thick sola and strongly developed B horizons. Thick, well developed, eluvial (Ae) horizons occur in stable positions. Thin Ah horizons are common under deciduous vegetation. Orthic Sombric Brunisols and Cumulic Regosols occur in minor amounts on avalanched segments. Orthic Humo-Ferric Podzols occur occasionally on forested segments and are associated with the altered, medium textured eolian (Eolian material B) veneers. A pedon illustrating Eluviated Dystric Brunisols of EN2 is described in Table 180 and shown in Color Plate 19.

Vegetation

Vegetation distribution on the EN2 Ecosite is governed by the frequency and intensity of avalanching. Avalanched segments dominate and are characterized by a heterogeneous complex of avalanche v.t.s including subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (S10), juniper-willow (L2), hairy wild rye-wild strawberry-fireweed (H5), fleabane-valerian (H16) plus intergrades, collectively termed Avalanche Complex 2. The S2 and L2 v.t.s are most abundant and extensive on EN2 but the other avalanche v.t.s plus intergrades occur occasionally. Heather-everlasting (L5) occurs in minor amounts. A plot representing vegetation of the pedon sample site described in Table 180 and illustrating S2 on EN2 avalanched segments is presented in Table 181 and Plate 108.

Unavalanched or infrequently avalanched segments may constitute up to 50% of EN2 tracts and occur as forested strips between avalanche tracks, and as patches along lower slopes fringing avalanche runout zones. The Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) and Engelmann spruce-subalpine fir/heather (O10) v.t.s are most abundant on these segments. The O4 v.t. occurs on dry southerly aspects; O10 favors more moist conditions. Engelmann spruce-subalpine fir/grouseberry (C15) occurs as an accessory v.t. and is common at low elevations. Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) also occurs occasionally and replaces C15 in northern Jasper, north of the range of *Vaccinium scoparium*. Subalpine larch-subalpine fir/grouseberry-everlasting (C23) occurs occasionally in southern Banff both on unavalanched, forested strips and as a stunted variant on avalanche path margins.

Unvegetated portions, associated with rubbly colluvium and Regosolic soils on intensely active sites, may constitute up to 50% of EN2 tracts or up to 80% of tracts mapped as EN2+T or EN2+CR.

Discussion

In terms of landform surface expression, physiographic position, and vegetation cover, EN2 resembles the Wildflower 2 (WF2) and Whitehorn (WH3) Ecosites. However, in contrast to the Colluvium A characterizing EN2, WF2 occurs on colluvial landforms consisting of calcareous, medium textured colluvium (Colluvium C) and WH3 occurs on noncalcareous, medium textured colluvium (Colluvium B). Also, WF2 has Eutric Brunisols and a significant amount of Regosolic soils. The WH3 Ecosite, like EN2, has Dystric Brunisols but both sola and Ae horizons are thinner in the former. Regosolic soils are more extensive on WH3 than on EN2. The EN1 and EN3 Ecosites are differentiated from EN2 primarily by vegetation differences (Table 177) that reflect varying type and degree of colluvial activity. The Fairview 1 (FV1) Ecosite, where it occurs on noncalcareous, coarse textured colluvium (Colluvium A), is the Lower Subalpine counterpart of EN2.

EN3 - ENDLESS CHAIN 3 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, EN3, encompasses blankets and veneers of noncalcareous, coarse textured colluvium (Colluvium A) overlying inclined bedrock on steep valley walls. Exposed bedrock escarpments are subdominant. Colluviation, in the form of surface or soil creep, is characteristic and influences soil and vegetation development. A soil pattern characterizes EN3 in which Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols and Orthic Regosols are subdominant. A charcteristic vegetation pattern occurs in which Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) is dominant and Engelmann spruce-subalpine fir/heather (O10) is subdominant.

Geomorphology

The EN3 Ecosite occurs on shallow, discontinuous, colluvial landforms consisting of noncalcareous, coarse textured colluvium (Colluvium A). Exposed bedrock forms the subdominant portion of the landscape. Underlying and exposed bedrock is predominantly Gog Group quartzites although three EN3 tracts north of Cascade Mountain in Banff overlie and contain material derived from quartz sandstone of the Rocky Mountain Group. Geomorphic activity on EN3 primarily consists of shallow colluviation, varying in intensity across the landscape. Avalanching and related processes also occur on tracts mapped as EN3A but usually in channeled tracks. Sheet erosion is extensive but of minor consequence. Locally, stream erosion in avalanched couloirs is more important to soil and vegetation development. Veneers of altered, medium textured eolian material (Eolian material B) occur sporadically, associated with stable sites. Rubble without fine earth material for soil development is common in some EN3 tracts, particularly those occurring below steep rock walls.

Topographically, EN3 displays long, linear, inclined slopes commonly ranging from 45 to >100%. These slopes consist of discontinuous colluvial veneers and blankets broken by patches of exposed bedrock. Tracts of EN3 with complex topography have linear slopes whose continuity is broken by one or more exceptionally steep bedrock escarpments. Tracts of EN3A often have couloirs that encompass avalanche tracks, avalanche starting zones, and associated intermittent stream channels. Tracts mapped as EN3F occur occasionally and are characterized by failed slopes that include failure of the unconsolidated material and partial failure of underlying bedrock.

Soils

Soils of the EN3 Ecosite are distributed in a pattern reflecting degree and intensity of surface colluviation and, to a lesser extent, avalanching. Eluviated Dystric Brunisols are dominant and reflect low intensity, infrequent colluvial and erosional processes. Orthic Dystric Brunisols and Orthic Regosols are subdominant. Orthic Dystric Brunisols occupy localities where surface modification is weak but eluvial (Ae) horizon development is retarded or has been destroyed. On localities where geomorphic activity is frequent and in-

tense, Orthic Regosols are abundant. These localities include unvegetated rubbly sites and couloirs. Lithic phases of EN3 soils are common.

Soils of the EN3 Ecosite are rapidly to well drained and reflect, in their development, the acidic, rapidly pervious parent material. The Brunisolic soils have thick sola and strongly developed B horizons. Thick, well developed, eluvial (Ae) horizons occur in stable positions. The Orthic Regosols may have thin Ah horizons. Orthic Humo-Ferric Podzols occur occasionally and are associated with altered, medium textured eolian (Eolian material B) veneers on stable sites. A pedon illustrating Eluviated Dystric Brunisols of EN3 is described in Table 182.

Vegetation

Vegetation of the EN3 Ecosite is distributed in a pattern reflecting degree of colluvial activity, drainage, and elevation. Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) is dominant and occurs characteristically on more active, subxeric sites on southerly aspects. Engelmann spruce-subalpine fir/heather (O10) is subdominant and occurs more extensively on northerly aspects, at higher elevations, and on less active sites.

Juniper-willow (L2) and subalpine larch-subalpine fir/grouseberry-everlasting (C23) are accessory v.t.s, with L2 occurring on actively colluviating and avalanched localities. The C23 v.t. is important on several EN3 tracts of southwestern Banff, south of Hector Lake and Pipestone Pass. Heather-everlasting (L5) occurs in minor amounts but occasionally is quite common with tree islands (O10) on relatively stable, high elevation EN3 tracts. Also in minor amounts, subalpine fir-willow (S2) is associated with avalanched portions (EN3A). A plot representing vegetation of the pedon sample site described in Table 182 and illustrating O4 on EN3 is presented in Table 183 and Plate 109.

Unvegetated portions, associated with rubbly colluvium and Regosolic soils on intensely active sites, may constitute up to 50% of EN3 tracts, or up to 80% of tracts mapped as EN3+CR.

Discussion

In terms of landform surface expression, physiographic position, and vegetation cover, EN3 resembles the Wildflower 3 (WF3) and Whitehorn 5 (WH5) Ecosites. However, in contrast to the Colluvium A characterizing EN3, WF3 occurs on colluvial landforms consisting of calcareous, medium textured colluvium (Colluvium C), and WH5 occurs on noncalcareous, medium textured colluvium (Colluvium B). Also, WF3 has Eutric Brunisols. WH5, like EN3, has Dystric Brunisols but both sola and Ae horizons are thinner in the former. In addition, Regosolic soils are more extensive on WF3 and WH5 than on EN3. The EN1 and EN2 Ecosites are differentiated from EN3 primarily by vegetation differences (Table 177) that reflect varying type and degree of colluvial activity.

FR - FIRESIDE ECOSECTION

The Fireside (FR) Ecosection encompasses fluvial landforms comprised of calcareous, coarse, stratified fluvial material (Fluvial material B) in the Montane Ecoregion. Brunisolic soils associated with lodgepole pine forests characterize FR. This Ecosection is found mainly on the lower slopes of the Athabasca River valley in Jasper and the Bow and North Saskatchewan River valleys in Banff. It also occurs on the lower slopes of the Miette, Snake Indian, Maligne, and Rocky River valleys and the Moosehorn Creek valley in Jasper. In Banff, FR also occurs in the Lake Minnewanka valley.

Only one Ecosite (FR1) is recognized within the FR Ecosection. Its general features are outlined in Table 184.

FR1 - FIRESIDE 1 ECOSITE

Ecosite Concept

The FR1 Ecosite is characterized by fluvial fans and aprons consisting of calcareous, coarse, stratified fluvial material (Fluvial material B). Orthic and Eluviated Eutric Brunisols typify the soil component. Vegetation cover is dominated by the lodgepole pine/buf-

faloberry/showy aster (C6) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s.

Geomorphology

The Montane Ecosite, FR1, encompasses fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Irregular surfaces produced by channeling (Eroded modifier, C.S.S.C. 1978b) are common features. These fluvial deposits are generally moderately to extremely calcareous and reflect the calcareousness of their source materials. These materials are eroded from morainal, colluvial and rock slopes above. An exception occurs in the Miette River valley in Jasper where fluvial landforms comprised of noncalcareous, coarse, stratified fluvial material (Fluvial material A) are mapped as FR1. Here absence of lime is controlled by the lithology of the surrounding Miette Group bedrock. Geomorphologically, FR1 tracts are relatively stable as indicated by the degree of soil development.

Topographically, FR1 displays linear slopes on fans and aprons. Slopes commonly range from 2 to 30% with the gentler slopes confined to apron and fan toes on valley floors. Slope continuity is often broken by abandoned and active stream channels including their natural levee margins (Eroded modifier, C.S.S.C. 1978b).

Soils

Soils of the FR1 Ecosite are well drained and the degree of development of these soils reflects geomorphic stability. Orthic and Eluviated Eutric Brunisols are the dominant soils. Orthic and Cumulic Regosols are accessory soils that reflect a more active geomorphic environment. These soils occur near present and abandoned stream channels and may be subject to erosion or flooding during spring run-off and periods of high precipitation. Eutric Brunisols with Btj horizons indicating luvisolic tendencies were found on a few FR1 tracts in the Redearth and Whiskey Creek areas of Banff and the Mount Kerkeslin area of Jasper. These particular tracts tend to be finer textured at the surface than their modal FR1 counterparts. A pedon illustrating Orthic Eutric Brunisols of FR1 is described in Table 185 and shown in Color Plate 20. This pedon was sampled on the Sundance Creek fan in Banff.

Vegetation

The FR1 Ecosite is dominated by the closely related lodgepole pine/buffaloberry/showy aster (C6) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s that reflect the extensive effects of fire in the Montane Ecoregion. In Banff, lodgepole pine/dwarf bilberry (C9) occurs as an accessory v.t. on tracts of FR1 in

the Bow River valley between Johnston Canyon and the Banff townsite. In Jasper, the lodgepole pine/green alder/feathermoss (C10) and lodgepole pine/feathermoss (C11) v.t.s occur in minor amounts on FR1 tracts in the Miette River Valley. A stand illustrating the C6 v.t. on FR1 is described in Table 186 and shown in Plate 110 and represents the vegetation at the pedon sample site described above in Table 185.

Discussion

The FR1 Ecosite may appear similar to the Athabasca 1 (AT1) Ecosite but AT1 can be differentiated because of the coarser, more cobbly glaciofluvial materials. The Altrude 1 (AL1) Ecosite is the Lower Subalpine counterpart of FR1.

FV - FAIRVIEW ECOSECTION

The Fairview (FV) Ecosection encompasses steep, usually linear, colluvial landforms comprised of either noncalcareous, coarse textured colluvium (Colluvium A) or noncalcareous, medium textured colluvium (Colluvium B) in the Lower Subalpine portion of the Subalpine Ecoregion of Banff and Jasper. It occurs predominantly in the Main Ranges on or below steep, rocky, valley walls that are geologically dominated by noncalcareous strata.

Varying type and degree of colluvial activity, aspect, exposure, and lithology govern soils and vegetation development and distribution. The FV Ecosection is characterized by Dystric Brunisols associated with hetergeneous avalanche complex vegetation and Engelmann spruce-subalpine fir forest.

The Ecosites (FV1, FV2) are recognized within the FV Ecosection and are separated primarily on vegetation differences. Table 187 outlines the general features of the FV Ecosites. Fig. 40 for the Endless Chain (EN) Ecosection shows, schematically, the physiographic positions of the FV1 and FV2 Ecosites.

FV1 - FAIRVIEW 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, FV1, encompasses avalanched colluvial landforms comprised of either noncalcareous, coarse textured colluvium (Colluvium A) or noncalcareous, medium textured colluvium (Colluvium B). These exist as blankets and veneers overlying inclined bedrock on steep valley walls and as aprons along slope bases at major slope breaks. Snow avalanching is characteristic and governs the distribution of vegetation and, to a lesser extent, soils. A soil pattern in which Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols and Orthic Regosols are subdominant typifies and the soil component of FV1. Avalanched segments dominate and are characterized by a heterogeneous complex of v.t.s that include subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (S10), hairy wild rye-wild strawberry-fireweed (H5), aspen/hairy wild rye-showy aster (C22) plus intergrades collectively called Avalanche Complex 1. Forested strips and patches between avalanche tracks and fringing runout zones are subdominant and best represented by the Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/false azalea (C14) v.t.s.

Geomorphology

The FV1 Ecosite occurs on blankets, veneers and aprons comprised of either noncalcareous, coarse textured colluvium (Colluvium A) or noncalcareous, medium textured colluvium (Colluvium B). Source bedrock on FV1 tracts comprised of Colluvium A is predominantly Gog Group quartzite. Miette Group or noncalcareous Mesozoic strata dominate tracts comprised of noncalcareous, medium textured colluvium (Colluvium B). Several FV1 tracts contain admixtures of the two colluvial material genetic units. More than 50% of FV1 is modified by snow avalanching. Avalanching of such areal extent usually occurs with coalescing, unconfined avalanche paths, or as runout zones below the length of a cliff. Gully-like channeled avalanche tracks (chutes) are common as well. Perla and Martinelli (1975) define snow avalanche zone terminology.

Genetic material stability within FV1 tracts is greatest on portions unaffected by avalanching, but the unconfined avalanche tracks are almost as stable. Together these components make up a majority of the area of most FV1 tracts. Instability is of two kinds. Erosion of unconsolidated material occurs, though infrequently, on steep avalanche starting zones

Table 187 General features of the Fairview (FV) Ecosites.

Ecosite	Landform	Soils	Vegetation
FV1	Colluvium A,B; blanket, veneer, apron	Dystric Brunisol > Regosolic	Avalanche Complex 1 > Engelmann spruce-subalpine fir forest
FV2	Colluvium A,B; blanket, veneer	Dystric Brunisol	Engelmann spruce-subalpine fir forest

and on walls of channeled tracks. It is usually evidenced by sparsely vegetated patches. Deposition is a more common process and frequently includes material derived from bedrock exposures high on, or above the FV1 tract. Talus occurs as part of the FV1 Ecosite concept, its location and extent controlled by the cliffs above. Material carried by avalanching is distributed downslope to gentler runout zones. Colluvial material is modified by intermittent streams below couloirs and on avalanche runout zones. Fluvial deposits, occurring as thin veneers, and layers interbedded with colluvium, are most abundant below channeled tracks and couloirs. This material is a weakly sorted variant of noncalcareous, coarse, stratified fluvial material (Fluvial material A), and like the colluvium, is either medium or coarse textured with a high content of angular coarse fragments. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically on the subdominant unavalanched segments of the landscape. Rubble without fine earth material for soil development is common on some FV1 tracts, particularly, those occurring as aprons below steep rock walls.

Topographically, FV1 displays long, linear inclined slopes commonly ranging from 45 to 90%. Slopes <45% occur on lower slopes and toes of colluvial aprons. Surface form is controlled by deposition and underlying bedrock. The colluvial material deposits are generally shallowest (veneers) at the tops of slopes and deepen downslope to form aprons along slope bases at major slope breaks. Colluvial aprons also occur below steep rock walls. Shallow channels and accompanying levees, constructed by intermittent streams, are often associated with a wide range of gullying on avalanche tracks. Colluvial veneer landforms dominate tracts mapped as FV1X.

Soils

Soil distribution and development on the FV1 Ecosite is related to genetic material stability as influenced by avalanching and associated processes. A soil pattern, in which Eluviated Dystric Brunisols are dominant and Orthic Dystric Brunisols and Orthic Regosols are subdominant, characterizes FV1. Eluviated Dystric Brunisols occur where geomorphic activity is least frequent or intense, especially on the forested segments or avalanched segments without cliffs above. Orthic Dystric Brunisols occupy localities where surface modification is weak but sufficient to retard or destroy eluvial (Ae) horizon development. On localities where erosion or deposition is frequent and intense, Orthic Regosols are abundant.

Soils of the FV1 Ecosite are rapidly to moderately well drained and reflect, in their development, their acidic, medium and coarse textured parent materials. The Brunisols have moderately to strongly developed B horizons. The Eluviated Dystric Brunisols have well developed eluvial (Ae) horizons. Some Orthic Dystric Brunisols and Orthic Regosols may have thin Ah horizons. Orthic Humic Regosols occur in minor amounts on avalanched segments; Orthic Humo-Ferric Podzols occur occasionally on forested segments and are associated with veneers of altered, medium textured eolian material (Eolian material P). Lithic soil phases dominate tracts mapped as FV1X. A pedon illustrating Eluviated Dystric Brunisols of FV1 is described in Table 188 and shown in Color Plate 21. This pedon was sampled on an east-facing slope above Cirque Lake in Banff.

Vegetation

Vegetation distribution on the FV1 Ecosite is governed by the frequency and intensity of avalanching. Avalanched segments dominate and are characterized by a heterogeneous complex of v.t.s that include subalpine fir-willow (S2), willow-dwarf birch-shrubby cinquefoil (S10), hairy wild rye-wild strawberry-fireweed (H5), aspen/hairy wild rye-showy aster (C22), plus intergrades. The S2 v.t. is most abundant and extensive on FV1 but the other avalanche v.t.s plus intergrades occur occasionally. A plot illustrating the S2 v.t. on avalanched segments of FV1 is described in Table 189 and shown in Plate 111 and represents vegetation at the pedon sample site described above in Table 188. Tracts of FV1 that have been modified by fire, mapped as FV1B, occur between Fortress Lake and the confluence of the Athabasca and Chaba Rivers in Jasper. Unavalanched or infrequently avalanched segments may constitute up to 50% of FV1 tracts and occur as forested strips between avalanche tracks, and as patches along lower slopes fringing avalanche runout zones. The Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/false azalea (C14) v.t.s are most abundant on these segments. Unvegetated portions are associated with rubbly colluvium and Regosolic soil on intensely active sites.

Discussion

In terms of landform surface expression, physiographic position and vegetation cover, FV1 resembles the Sawback 1 (SB1) Ecosite. However, rather than Colluvium A and B characterizing FV1, SB1 occurs on colluvial landforms consisting of calcareous, medium textured colluvium (Colluvium C) and has Eutric, rather than Dystric, Brunisols. The FV1 Ecosite is separated from the FV2 Ecosite primarily on vegetation differences (Table 187) that reflect

varying type and degree of colluvial activity. The Endless Chain 2 (EN2) and Whitehorn 3 (WH3) Ecosites are the Upper Subalpine counterparts of FV1.

FV2 - FAIRVIEW 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, FV2, encompasses blankets and veneers consisting of either noncalcareous, coarse textured colluvium (Colluvium A) or noncalcareous, medium textured colluvium (Colluvium B) overlying inclined bedrock on steep valley walls. The soils are dominated by Orthic and Eluviated Dystric Brunisols and suggest by their development that colluviation is not sufficiently active to prevent profile development. Eluviated Dystric Brunisols are the most abundant soils associated with FV2. Likewise, vegetation is successionally mature and is dominated by the Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/false azalea (C14), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. The C13 v.t. is most abundant.

Geomorphology

The FV2 Ecosite occurs on blankets and veneers consisting of either noncalcareous, coarse textured colluvium (Colluvium A) or noncalcareous, medium textured colluvium (Colluvium B) overlying inclined bedrock on steep valley walls. Source bedrock on FV1 tracts consisting of Colluvium A is predominantly Gog Group quartzite. Miette Group or noncalcareous Mesozoic strata dominate tracts characterized by Colluvium B. Several FV2 tracts contain admixtures of the two colluvial genetic material units. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically and are most abundant on FV2 tracts of western Banff and southwestern Jasper. Erosional and colluvial processes have removed or incorporated most of the eolian material which provides the evidence of wind blown accumulations. Till occasionally underlies colluvial material along lower, more gentle slopes of FV2 tracts. Thin fluvial deposits, generally a weakly sorted variant of noncalcareous, coarse, stratified fluvial material (Fluvial material A), occasionally are interbedded with colluvium on avalanched portions of tracts mapped as FV2A.

Topographically, FV2 displays long, linear, inclined slopes commonly ranging from 45 to 90%. Surface form is controlled by deposition and underlying bedrock. The colluvial deposits are generally shallowest (veneers) at the tops of slopes and deepen downslope. Colluvial aprons occur occasionally along slope bases at major slope breaks.

Soils

The soils of the FV2 Ecosite reflect in their development, the acidic, medium and coarse textured parent materials and stable geomorphic conditions. Eluviated Dystric Brunisols are more common than Orthic Dystric Brunisols but the latter dominates a few tracts. These well to moderately well drained soils have moderately to strongly developed B horizons. Well developed eluvial (Ae) horizons are generally present but Orthic Dystric Brunisols occur in localities where surface disturbances are sufficient to inhibit or destroy Ae development. Orthic Humo-Ferric Podzols are accessory soils and are associated with veneers of altered, medium textured eolian material (Eolian material B). A pedon illustrating Eluviated Dystric Brunisols characterizing FV2 is described in Table 190 and shown in Color Plate 22. This pedon was sampled on a west-facing slope above the south end of Peyto Lake in Banff.

Vegetation

Vegetation cover of the FV2 Ecosite reflects stable geomorphic conditions. The Engelmann spruce-subalpine fir/feathermoss (C13), Engelmann spruce-subalpine fir/false azalea (C14), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s are dominant. The C13 v.t. is the most abundant but some FV2 tracts are dominated by C14 or C21. Tracts of FV2 that have been modified by

Discussion

In terms of landform surface expression, physiographic position, and vegetation cover, FV2 resembles the Sawback 2 (SB2) Ecosite. However, rather than the Colluvium A and B characterizing FV2, SB2 occurs on landforms consisting of calcareous, medium textured colluvium (Colluvium C) and also has Eutric Brunisols and a significant amount of Regosolic soils rather than Dystric Brunisols. The FV1 Ecosite is separated from FV2 primarily by vegetation differences (Table 187) that reflect varying type and degree of colluvial activity. The Endless Chain 1 (EN1) and Whitehorn 2 (WH2) Ecosites are the Upper Subalpine counterparts of FV2.

GA - GARONNE ECOSECTION

The Garonne (GA) Ecosection encompasses hummocky colluvial landforms comprised of calcareous, medium textured landslide material in the Montane Ecoregion. Brunisolic and Regosolic soils associated with lodgepole pine forest characterize GA. The only examples of this Ecosection in each park occur on the lower slopes of the Athabasca River valley in the vicinity of Garonne Creek in Jasper and, in Banff, on the lower slopes of the Bow River valley between Hillsdale and Johnston Creek. The GA Ecosection is represented by only one Ecosite (GA1) and its general features are outlined in Table 192 and Plate 113.

GA1 - GARONNE 1 ECOSITE

Ecosite Concept

The GA1 Ecosite is characterized by a calcareous, medium textured, hummocky colluvial landform (landslide) with rapidly to well drained Orthic Eutric Brunisols and Orthic Regosols, and with lodgepole pine forest.

Geomorphology

The GA1 Ecosite is characterized by weakly to extremely calcareous, stabilized landslide (colluvial) deposits with hummocky relief. Slopes are complex and commonly range from 15 to 45%. These postglacial deposits are medium textured with a high content of variable sized angular and subangular coarse fragments. They also have a high proportion of the surface occupied by stones and boulders. In Jasper, the slide originated from the

west face of a mountain in the Colin Range, depositing limestone debris downslope. The upper portion of this landslide overlies a till bench whereas the lower portion overlies fluvial deposits. The upper and lower portions are separated by a steep till slope mapped as NY3. In Banff, the landslide originated from the west face of Mount Ishbel. The upper portion of this slide failed en masse whereas the lower portion crumbled and deposited debris down slope to and across the Bow River. The debris of this slide is dominantly calcareous siltstones and shales of the Sulphur Mountain Formation. The colluvial material is overlain by altered, medium textured eolian material (Eolian material B) in Banff and by the calcareous, medium textured eolian material (Eolian material A) in Jasper.

Soils

The GA1 Ecosite is characterized by rapidly to well drained Orthic Eutric Brunisols and Orthic Regosols on weakly to extremely calcareous parent materials. These soils exhibit silt loam to loam (medium) textures throughout the solum. Orthic Regosols are more common than Orthic Eutric Brunisols in Jasper and are distinguished by the presence of carbonates in all soil horizons due to a calcareous, medium textured eolian material (Eolian material A) overlying the colluvium. In Banff, Orthic Eutric Brunisols are dominant and have an acid to neutral upper solum (Eolian material B). A pedon illustrating Orthic Eutric Brunisols of GA1 is described in Table 193 and shown in Color Plate 23.

Vegetation

The GA1 Ecosite is dominated by subxeric to mesic v.t.s: lodgepole pine/juniper/bearberry (C3), lodgepole pine/buffaloberry/showy aster (C6), and lodgepole pine/buffaloberry/twinflower (C19). The Douglas fir/hairy wild rye (C1) v.t. occupies a smaller area. In Jasper, the C3 v.t. is predominant, with the C1 v.t. less common, whereas in Banff, the C6 and C19 v.t.s. are predominant. The aspen/hairy wild rye-peavine (C16) and C1 v.t.s. occur in minor amounts as an accessory in Banff. On steep, exposed slopes in Banff, minor amounts of bluebunch wheatgrass-hairy wild rye-showy aster (H19) v.t. occur. A stand illustrating the C19 v.t. on GA1 is described in Table 194 and shown in Plate 21.

Discussion

The GA1 Ecosite has only one mappable occurrence within each park. The GA1 Ecosite is defined as occurring in the Montane Ecoregion which distinguishes it from the similar Ishbel 1 (IB1) Ecosite which occurs in the Lower Subalpine.

GT - GOAT ECOSECTION

The Goat Ecosection encompasses steeply sloping morainal landforms comprised primarily of calcareous, medium textured till (Till C) throughout the Lower Subalpine portion of the Subalpine Ecoregion in Banff and Jasper. Erosional processes, including surface erosion (e.g. gullying, sheet erosion, shallow colluviation) and undercutting by streams, are or have recently been active and control the landscape features. The GT Ecosection occurs primarily on valley walls, benchlands and narrow valley floors.

Weakly to moderately developed Eutric Brunisols, often exhibiting rudimentary luvisolic tendencies, are generally dominant. However, Regosolic soils, reflecting surface instability and erosion, are subdominant. Vegetation cover is characterized by dry to moist lodgepole pine forest, white spruce open forest, mixed coniferous open forest, dry grassland, and low shrub-herb meadow. Distribution of vegetation types is related to degree of surface erosion, steepness of slope, exposure, and aspect.

Two Goat Ecosites are differentiated. The GT1 Ecosite generally has unidirectional slopes with moderate erosion and open forests. The GT2 Ecosite displays a landscape pattern (primarily vegetational) governed by steepness of slope, exposure, aspect, and degree of erosion. For convenience and standardization, the two distinctly different GT2 segments are termed northerly and southerly aspects. The general features of the Goat Ecosites are presented in Table 195. Figs. 41 and 52 show the physiographic positions of GT1 and GT2. These figures are applicable to Front Range areas of Banff and Jasper, but GT1 also occurs in the Main Ranges.

GT1 - GOAT 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, GT1, occurs on morainal blankets consisting of calcareous, medium textured till (Till C) overlying inclined bedrock on valley walls. Its long, steep, linear slopes are characterized by surface erosion including primarily gullying, sheet erosion, and shallow colluviation (soil creep). These modifying processes influence soil and vegetation development. Thus, a soil pattern in which Orthic Eutric Brunisols are dominant and Orthic Regosols are subdominant typifies the soil component of GT1. Vegetation is characterized by open forest, best represented by an open forest variant of the lodgepole pine/juniper/bearberry (C3) v.t., with lesser amounts of Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) and white spruce/juniper/bearberry (O17) v.t.s. The GT1 Ecosite occurs primarily on southerly aspects and is associated with calcareous strata throughout Banff and Jasper.

Geomorphology

The GT1 Ecosite is typified by morainal blankets consisting of calcareous, medium textured till (Till C) overlying inclined bedrock. Due to the active and recently active erosion on these slopes, eolian veneers are usually absent but other erosion products have accumulated locally. Calcareous, coarse, stratified fluvial material (Fluvial material B) occurs, usually along the bases of gullied slopes. Veneers of calcareous, medium textured colluvium (Colluvium C), derived primarily from the till, are common on and below localities where shallow colluviation is or has recently been occurring.

Topographically, GT1 displays long linear slopes of till mantling inclined bedrock that forms valley walls. Slopes commonly range from 45 to 70% and are usually dissected by subparallel gullies. Small fluvial fans and aprons emanating from gully mouths along slope bases may be included in GT1 tracts. Erosional products also occur locally as fluvial and colluvial veneers. A few GT1 tracts have irregular, hummocky, or ridged surfaces with slopes ranging from 30 to 70%. These tracts are situated on rounded spurs (shoulders), where surface form is controlled by underlying bedrock, and on failed slopes. Morainal veneers occur occasionally on both linear and irregular slopes and dominate on GT1X tracts. Bedrock outcrops occur sporadically and are common on tracts mapped as GT1+R.

Soils

Soil development and distribution reflect the surface erosional processes that characterize GT1. The soil pattern, in which Orthic Eutric Brunisols are dominant and Orthic Regosols are subdominant, reflects varying degrees of erosion across the rapidly to well drained landscape. Localities where erosion is slight, intermittent, or has recently ceased, have Orthic Eutric Brunisols. These soils generally have weakly developed Bmk horizons. Eluvial (Ae) horizons are absent or weakly developed. Eluviated Eutric Brunisols, as accessory soils, and Brunisolic Gray Luvisols, in minor amounts, occur on the most stable localities within tracts mapped as GT1.

Table 195 General features of the Goat (GT) Ecosites.

Ecosite	Landform	Soils	Vegetation

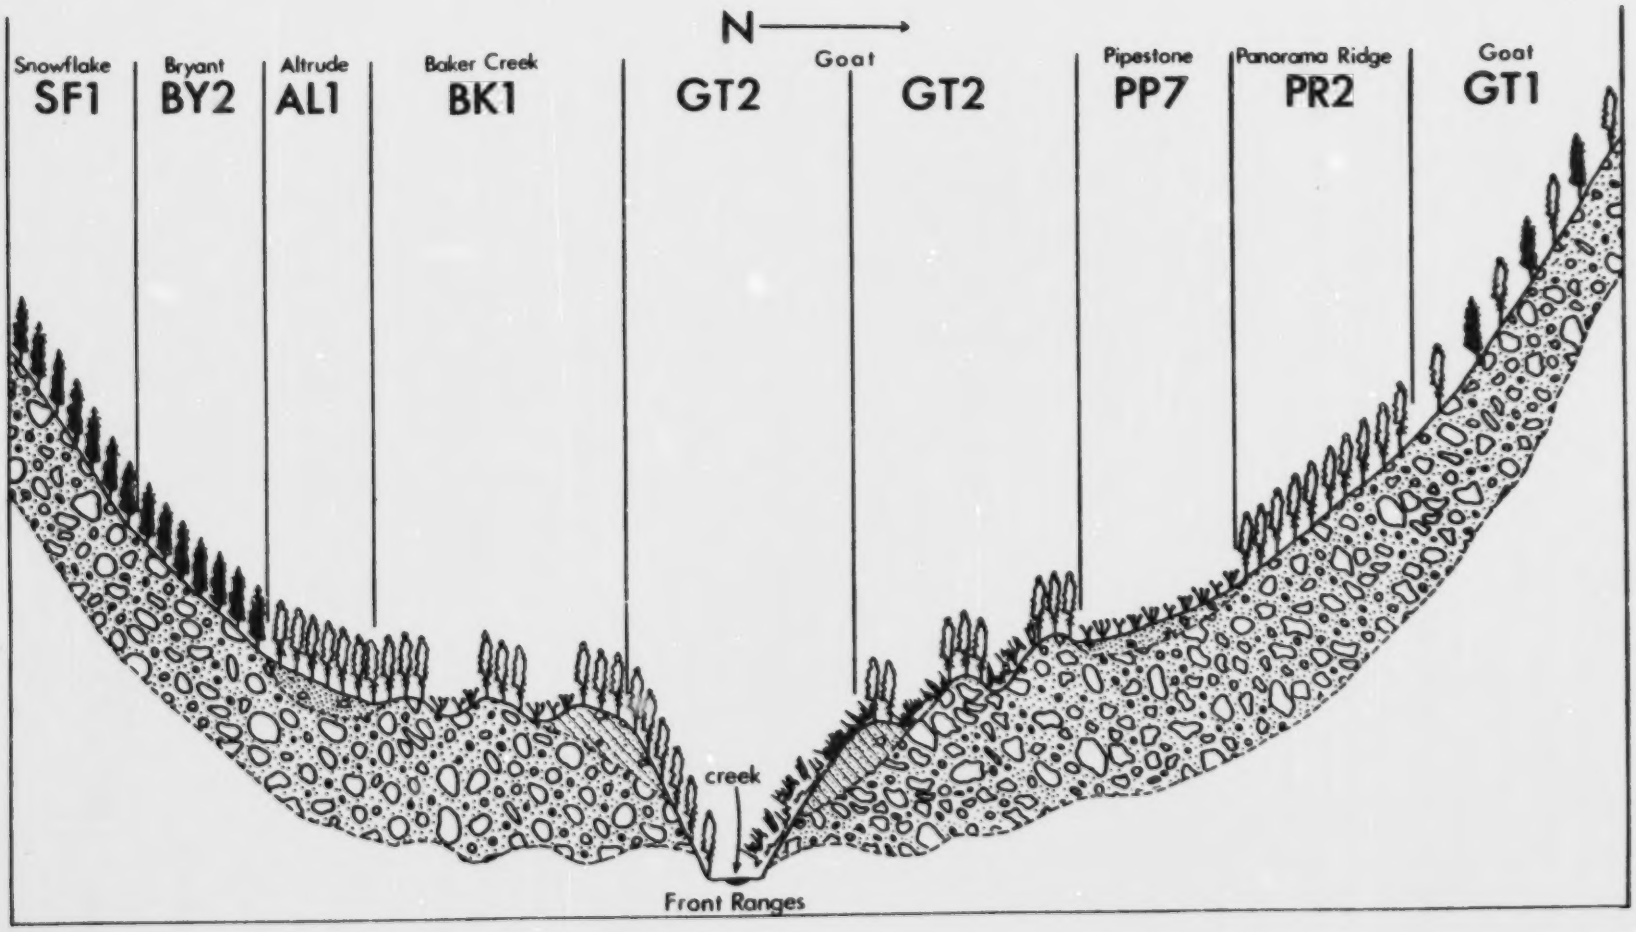
GT2	Till C; blanket, inclined	Northerly: Eutric Brunisol Southerly: Regosolic	Northerly: lodgepole pine forest Southerly: dry grassland, low shrub-herb meadow

Figure 41 Landscape schematic showing the relationship of the Goat (GT1, GT2) Ecosites to other Ecosites.



Orthic Regosols occur on more severely eroded localities where fresh weathering surfaces are maintained. Orthic Humic Regosols and Cumulic Regosols occur in minor amounts in localities where erosional products accumulate.

A pedon illustrating Orthic Regosols of GT1 is described in Table 196 and shown in Color Plate 24. This profile and its associated vegetation occur as a small area in a PR2F tract. Because of map scale limitations, small areas resembling GT1 occur in tracts mapped as Panorama Ridge 2 (PR2). Till at this site is less compact than normal due to the massive slope failure that affected the tract.

Vegetation

Vegetation development and distribution reflect surface erosional processes, exposure, and southerly aspects. An open forest variant of the lodgepole pine/juniper/bearberry (C3) v.t. and the Engelmann spruce-subalpine fir-white-bark pine-lodgepole pine (O4) and white spruce/juniper/bearberry (O17) v.t.s dominate GT1. The C3 open forest variant is most abundant but a few GT1 tracts are dominated by O4 and O17. The central concept of closed forest C3, lodgepole pine/buffaloberry/showy aster (C6), and lodgepole pine/buffaloberry/twinflower (C19) commonly occupy stable, protected sites on the landscape. White spruce-Douglas fir/feathermoss (C5), Douglas fir/juniper/bearberry (O5) and shrubby cinquefoil/bearberry-northern bedstraw (L1) occur in minor amounts. Modification of the vegetation by avalanching, mapped as GT1A, and by recent fire, mapped as GT1B, has occurred in some areas.

A plot illustrating the C3 open forest variant on GT1 is presented in Table 197 and Plate 114. This plot and its associated soil occur as a small area in a PR2F tract. Because of map scale limitations, small areas resembling GT1 occur in tracts mapped as Panorama Ridge 2 (PR2).

Discussion

In terms of landform, GT1 resembles the Panorama Ridge 2 (PR2) Ecosite. The PR2 Ecosite, however, is dominated by Brunisolic and Luvisolic soils occurring under lodgepole pine closed forest, features that indicate significantly less surface erosion. Several tracts mapped as PR2 contain, because of map scale limitations, actively eroding or recently eroded localities that resemble GT1 in terms of soil and vegetation. Similarly, portions of southerly aspect segments of the Panorama Ridge 4 (PR4) Ecosite resemble GT1. The Sawback 4 (SB4) Ecosite displays soils and vegetation similar to GT1 but occurs on very steep, linear, often rocky slopes dominated by veneers and blankets of calcareous, medium textured colluvium (Colluvium C). Slopes consisting of Colluvial material C frequently occur adjacent to and above GT1 tracts. The GT2 Ecosite is differentiated from GT1 by its compound landscape pattern involving pine forest on protected segments and treeless grassland and shrub-herb meadow on steep, exposed, unstable, southerly aspects (Table 195).

GT2 - GOAT 2 ECOSITE

Ecosite Concept

The Lower Subalpine GT2 Ecosite occurs on inclined and ridged morainal landforms consisting of calcareous, medium textured till (Till C). Surface expression reflects the down- and sidecutting activity of streams on valley floors or the underlying bedrock on valley walls and benchlands. Both soils and vegetation are found in a landscape pattern influenced by aspect, steepness of slope, exposure, and erosional processes such as gullying, sheet erosion, and shallow colluviation. On relatively stable, unexposed portions of the landscape ("northerly aspects"), well drained Orthic Eutric Brunisols occur with the mesic lodgepole pine/buffaloberry/twinflower (C19) and lodgepole pine/buffaloberry/showy aster (C6) v.t.s. The C19 v.t. is most abundant. Rapidly drained Orthic Eutric Brunisols and Orthic Humic Regosols with the subxeric hairy wild rye-junegrass-bearberry (H14) and shrubby cinquefoil/bearberry-northern bedstraw (L1) v.t.s dominate the exposed, steeply sloping, eroding, or recently eroded portions of southerly aspects. The H14 v.t. is most abundant on these essentially treeless localities, termed "southerly aspects". While exposed treeless segments are confined to steep southerly aspects, the forested segments occur on northerly aspects, ridge crests, depressions, and stable portions of southerly aspects. A few southerly aspect GT2 tracts are dominated by dry grassland. The GT2 Ecosite is confined to the Front Ranges, usually in association with Mesozoic strata, and is more extensive in Banff than in Jasper.

Geomorphology

The GT2 Ecosite is typified by morainal landforms consisting of calcareous, medium textured till (Till C) and, occasionally, non-calcareous, medium textured till (Till B). Glacial landforms comprised of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) on and adjacent to river banks are also included in the GT2 concept. Veneers of altered, medium textured eolian material (Eolian material B) occur sporadically on stable landscape segments and are absent on eroding and recently eroded southerly aspects. Alternately, erosional products from gullying, sheet erosion, and shallow colluviation have been distributed downslope, resulting in local occurrences of veneers and blankets of calcareous, medium textured colluvium (Colluvium C) and calcareous, coarse, stratified fluvial material (Fluvial material B), Fluvial material B also dominates the fluvial floodplains and terraces included in some tracts mapped as GT2 (Fig. 41).

Topographically, GT2 dislays either linear slopes or irregular, usually ridged surfaces. Two modes of formation are involved. On valley walls and benchlands, the inclined and ridged surfaces generally reflect underlying bedrock (Fig. 41), although deeper, strictly depositional, hummocky and ridged moraines also occur occasionally. The second type displays short, linear, erosional scarps produced by the down and sidecutting action of present and historical streams through the glacial deposits of valley floor benchlands and valley walls. Tracts representing this latter type are generally long, narrow, and sinuous and accommodate one or both stream banks depending on the areal extent of the fluvial landforms separating them. Ravine or canyon-like GT2 tracts include opposing stream erosional scarps plus the narrow fluvial floodplains and terraces that separate them (Fig. 41). On broad floors of major river valleys, the opposing river banks are usually mapped as two separate GT2 tracts when they are separated by wide, mappable, glaciofluvial or fluvial landforms (Fig. 52). Tracts of GT2 encompassing one straight to gently curving streambank have narrow aspect ranges throughout this length, but on sinuous stream banks all aspects can occur.

Slopes of the GT2 Ecosite commonly range from 30 to 90%, with linear ones usually being gullied. The steepest sloping tracts have been subjected to severe downcutting and surface erosion resulting in the exposure of bedrock. Bedrock walls are common on these gorge-like tracts (e.g. Tyrrell Creek in Banff). Ridge crest escarpments are common on GT2+R tracts. Morainal veneers occur occasionally on all types of terrain. Small fluvial fans, aprons, and veneers and colluvial veneers occur locally on eroded slopes.

Soils

Soils of GT2 are distributed in a pattern governed by aspect, steepness of slope, exposure, and erosional processes. Northerly aspects and other relatively stable portions of the landscape are dominated by Orthic Eutric Brunisols. These well drained soils generally have weakly to moderately developed B horizons that frequently display luvisolic tendencies. Genetically related Brunisolic and Orthic Gray Luvisols occur in minor amounts. Eluvial (Ae) horizons are weakly developed or absent, although Orthic Dystric Brunisols occur locally and are correlated with occurrences of noncalcareous, medium textured till (Till B). Eluviated Eutric Brunisols occur as accessory soils. Some exceptionally steep northerly aspects, exhibiting active colluviation locally, have Regosolic soils. Cryosolic soils occur occasionally on steep northerly aspects (e.g. Rock Creek area in Jasper). The pedons described in Table 301 and 305, for the Panorama Ridge 2 and 4 (PR2, PR4) Ecosites respectively, illustrate, except for degree of Ae development, soils of northerly aspect segments of GT2.

Exposed southerly aspects of GT2 are warmer, drier, steeper, and subject to more erosion. Surface erosional processes such as gullying, sheet erosion, and shallow colluviation (soil creep) are or have recently been active on these segments. Consequently, the rapidly drained, southerly aspect soils reflect these conditions and are dominated by Orthic Eutric Brunisols and Orthic Humic Regosols. Orthic Eutric Brunisols are associated with moderately eroded localities where removal is or has been more important than accretion. These soils generally have weakly developed Bmk or Bm horizons. Eluvial (Ae) horizons are absent but thin Ah horizons are common. Orthic Melanic Brunisols occur occasionally. On some GT2 tracts where the grassland vegetation has, in part, resulted from severe, recent fires (e.g. lower Tyrrell Creek valley), moderately developed Brunisolic soils (Bm and Btj horizons) dominate. Orthic Humic Regosols occur on more severely eroded localities where accretion is relatively important. They have thick Ahk horizons physically built up by the accumulation of organo-mineral erosional products. Orthic Regosols, occurring as accessory soils, may have thin Ah horizons and are generally associated with sites where removal is more dominant than accretion. Cumulic Humic Regosols also occur occasionally. A pedon illustrating Orthic Humic Regosols of exposed, unstable, southerly aspects of GT2 is described in Table 198 and shown in Color Plate 25.

Vegetation

Vegetation of GT2 is distributed in a pattern governed by aspect, steepness of slope, expo-

sure, and erosional processes. In some areas, recent and severe burning has also been a factor. Northerly aspects and other relatively stable, unexposed portions of the landscape are dominated by the mesic lodgepole pine/buffaloberry/showy aster (C6) and lodgepole pine/buffaloberry/twinflower (C19) v.t.s. The C19 v.t. is most abundant but C6 dominates northerly aspects of a few GT2 tracts. The closely related lodgepole pine/buffaloberry/grouseberry (C18) v.t. occurs in minor amounts. A few GT2 tracts (e.g. Panther River valley east of the Bare Range in Banff) have spruce forest best represented by the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica/twinflower/feathermoss (C31) v.t., on northerly aspects. Engelmann spruce-subalpine fir/feathermoss (C13) also occurs occasionally. Modification of forest vegetation by avalanching, mapped as GT2A, and recent fire, mapped as GT2B has occurred in some areas.

Exposed, unstable portions of southerly aspects are dominated by the subxeric hairy wild rye-junegrass-bearberry (H14) and shrubby cinquefoil/bearberry-northern bedstraw (L1) v.t.s. The H14 v.t. is the most abundant but some exposed southerly aspect segments are dominated by L1. White spruce/juniper/bearberry (O17) is an important accessory v.t. on some localities. Junegrass-pasture sage-wild blue flax (H6), wheatgrass-pasture sage (H7), and aspen/hairy wild rye-showy aster (C22) occur in minor amounts. A plot representing vegetation of the pedon sample site described above (Table 198) and illustrating L1 on exposed southerly aspects of GT2 is presented in Table 199 and Plate 115.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

The Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) and lodgepole pine/juniper/bearberry (C3) v.t.s occur sporadically, in minor amounts, on either segment of GT2. The O18 v.t. is associated with erosional slopes of both northerly and southerly aspects. The C3 v.t. occurs occasionally on ridge crests and other, relatively unexposed, stable sites. An open forest variant of C3 occurs ocassionally on the steep, exposed, southerly aspect, landscape segments.

A few GT2 tracts located on lower valley walls and benchlands (e.g. lower Tyrrell Creek valley in Banff) are dominated by the grassland (H14) segment and have only isolated patches of pine forest. Erosion on these tracts is not significant and Orthic Eutric Brunisols dominate. These features and their extensive distribution on such tracts is attributed to severe and recent (<100 years) fire. Slope, aspect, and exposure are helping maintain the grassland vegetation from succeeding to pine forest.

Discussion

The Lower Subalpine GT2 Ecosite is distinguished from similar Ecosites by a compound landscape pattern comprised of steep, exposed southerly aspects (resembling the Upper Subalpine TR2 and the Lower Subalpine SB5 Ecosites) and relatively unexposed, stable, northerly aspects (resembling the PR2 Ecosite). Map presentation of GT2 tracts at scales larger than 1:50,000 is invalid because the component segments would become mappable as separate Ecosites. Overall, GT2 resembles the Norquay 3 (NY3) Ecosite but NY3 occurs in the Montane Ecoregion. Also, PR4, like GT2, is a Lower Subalpine Ecosite but is characterized by spruce-fir forests on northerly aspects and lodgepole pine forests on southerly aspects, whereas GT2 is typified by lodgepole pine forests on northerly aspects and by grassland and low shrub-herb meadow on southerly aspects. The GT1 Ecosite is differentiated from GT2 by linear slopes and open forest vegetation in the former (Table 195).

HC - HECTOR ECOSECTION

The Hector Ecosection is complex and encompasses wet fluvial and fluviolacustrine landforms throughout the Lower Subalpine portion of the Subalpine Ecoregion in Banff and Jas-

per. Level plains, aprons, and fans are characteristic of Hector Ecosites. These landforms consist of calcareous, coarse, stratified fluvial material (Fluvial material B), occasionally noncalcareous, coarse, stratified fluvial material (Fluvial material A), and calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B). The subdominant landform on some HC Ecosites consists of horizontal fens that thinly mantle the fluvial and fluviolacustrine materials on the wettest localities.

A complex set of genetically related Gleysolic, gleyed Regosolic, and Organic soils is characteristic, with the Gleysolic soils being dominant. Distribution of these soils is related to degrees of gleying and saturation and the frequency of material accretion by flooding. Various groupings of Engelmann spruce forest, Engelmann spruce-subalpine fir open forest, wet shrubby meadow, birch fen, wet shrub thicket, and sedge fen differentiate the three HC Ecosites as outlined in Table 200.

The HC Ecosection most often occurs on valley floors adjacent to creeks and rivers. Attendant high water tables account, in the main, for its wetness. Hector 1 and 4 (HC1, HC4) are shown, schematically, on valley floor and benchland positions in Figs. 33, 37, 40, and 52. The HC2 Ecosite occupies similar valley floor positions. Plates 116 and 117 show HC2 and HC4 tracts on the landscape. A few tracts occur on valley floor benchlands in groundwater discharge zones where surface accumulations and seepage contribute to the wet conditions. In eastern Banff and Jasper, HC1 and HC4 often occur on benchlands below Snowflake 1 (SF1) tracts.

HC1 - HECTOR 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, HC1, encompasses wet fluvial landforms dominated by forest vegetation. These landforms consist primarily of calcareous, coarse, stratified fluvial material (Fluvial material B) and occasionally of noncalcareous, coarse, stratified fluvial material (Fluvial material A). Surface expressions include level floodplains, aprons and fans. Many surfaces are channeled (Eroded modifier, C.S.S.C. 1978b). The subdominant landform consists of horizontal fens that thinly mantle the fluvial materials on ponded localities.

A complex set of genetically related soils, reflecting recently deposited parent material and varying degrees of gleying, saturation and organic matter accumulation, characterizes the HC1 Ecosite. These soils are best represented by a soil pattern in which Rego Gleysols are dominant and Gleyed Cumulic Regosols and Terric Mesisols are subdominant. Vegetation is also complex and is best represented by a pattern in which the Engelmann spruce/horsetail/feathermoss (C32) and Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6) v.t.s are dominant and the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s are subdominant.

Geomorphology

The HC1 Ecosite is typified by fluvial landforms consisting primarily of calcareous, coarse, stratified fluvial material (Fluvial material B). A few tracts are dominated by noncalcareous, coarse, stratified fluvial material (Fluvial material A). Weakly calcareous mixtures of the two fluvial deposits occur often. Glaciofluvial material, mainly calcareous, coarse textured glaciofluvial material (Glaciofluvial material B), occurs on tracts associated with glacial streams. Important accessory genetic materials, occurring as veneers or layers on or within the fluvial deposits, are calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) and, occasionally, altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A). The fluviolacustrine materials occur on what were backwater depositional localities on floodplains and as veneers on the

Table 200 General features of the Hector (HC) Ecosites.

Ecosite	Landform	Soils	Vegetation
HC1	Fluvial material A,B; level, apron, fan > horizontal fen	Gleysol > gleyed Regosol, Organic	moist Engelmann spruce forest, wet Engelmann spruce-subalpine fir forest > wet shrubby meadow, birch fen
HC2	Fluviolacustrine material B; level	Gleysol	sedge fen
HC4	Fluvial material A,B; level, apron, fan > horizontal fen	Gleysol > gleyed Regosol, Organic	wet shrubby meadow, birch fen, wet shrub thicket, sedge fen

fringes of fans and aprons. Organic soils frequently overlie fluviolacustrine material, both features indicating ponding by currentless, relatively stagnant water. The fluvial and fluviolacustrine deposits may contain reworked material originally deposited as altered, medium textured eolian material (Eolian material B). Various tills underlie the fluvial deposits at shallow depths on some localities. Small morainal outcrops occur sporadically.

Soils of the HC1 Ecosite are usually thinly mantled by peat derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally wood fragments may be found. Where the peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b) recognizing that in some localities fen vegetation has been succeeded by open forest. The fen peat is underlain, within the control section, by the fluvial and fluviolacustrine deposits. On some sites Eolian material B containing volcanic ash is preserved in thin layers at or near the base of organic deposits.

Topographically, HC1 displays gentle linear slopes on level floodplains, aprons, and fans. Slopes commonly range from 0 to 9%. Tracts with complex slopes have irregular surfaces reflecting, in part, underlying morainal landforms. Slope continuity is often broken by abandoned and active stream channels, including their natural levee borders (Eroded modifier, C.S.S.C. 1978b). Weakly expressed terracing (risers <1 m) is a minor feature on some floodplain tracts.

Soils

Soils of the HC1 Ecosite are complex and reflect recently deposited parent material and varying degrees of gleying, saturation, and organic matter accumulation. These imperfectly, poorly, and very poorly drained soils are best represented by a pattern in which Rego Gleysols are dominant and Gleyed Cumulic Regosols and Terric Mesisols are subdominant. The strength of gleying is variable and reflects varying degrees of water table fluctuation, lateral water movement, and seepage water aeration. Prolonged periods of saturation give strongly gleyed soils with little or no pedogenic horizonation (Rego Gleysols). Gleyed Cumulic Regosols and the accessory soils, Gleyed Regosols, Gleyed Eutric Brunisols, and Orthic Gleysols, occur where saturation periods are shorter and depth to the water table is greater. Pedogenic horizonation in the Regosolic soils is limited by active or recently active fluvial deposition. The Gleyed Eutric Brunisols and Orthic Gleysols occur on the oldest surfaces where sufficient time for B horizon development has elapsed. Favorable moisture, nutrient, and vegetation conditions have resulted in the accumulation of varying thicknesses of fen peat on most HC1 soils. Terric Mesisols occur where the peat is >40 cm thick. Other soils with subdominant humic or fibric layers and Humic Gleysols occur occasionally. Well to moderately well drained Brunisolic and Regosolic soils occupy sites where the fluctuating water table rarely reaches the control section. A pedon illustrating Rego Gleysols of HC1 is described in Table 201 and shown in Color Plate 26.

Vegetation

Vegetation of the HC1 Ecosite is complex and is best represented by a pattern in which the Engelmann spruce/horsetail/feathermoss (C32) and Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6) v.t.s are dominant and the dwarf birch-shrubby cinquefoil-willow/brown moss (S1) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s are subdominant. Generally associated with C32 are imperfectly to poorly drained soils, mainly Gleysols, gleyed Regosols, and gleyed Brunisols, that display comparatively dry surface conditions. Organic soil and C32 do not occur together. Vegetation types O6, S1, and S3 are associated with soils that are saturated to the surface. The S1 and S3 v.t.s. break up the closed to open forest continuity by occurring frequently in small patches. Their areal extent is low. A plot representing vegetation of the pedon sample site (Table 201) is presented in Table 202 and Plate 118.

Spruce/Labrador tea/brown moss (O11) and water sedge-beaked sedge (H11) are accessory v.t.s occurring on poorly to very poorly drained soils. The O11 v.t. is restricted to relatively low elevations (<1800 m) and is more abundant in Jasper. The H11 v.t. occurs in small patches on very poorly drained, ponded, level sites. Other accessory v.t.s include Engelmann spruce-subalpine fir/feathermoss (C13) and Engelmann spruce-subalpine fir/willow/hairy wild rye (O18) that are associated with imperfectly to well drained soils on localities where water table fluctuations only occasionally affect the control section. Black spruce-lodgepole pine/willow/sedge (C8), white spruce/buffaloberry/fern moss (C26), lodgepole pine/Labrador tea (C29), Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30), white spruce/shrubby cinquefoil/bearberry (O3), Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14), willow/cinquefoil (S8), sedge-saxifrage (H3), and yellow dryad-willow herb (H8) are v.t.s occurring in minor amounts on HC1. Modification of HC1 vegetation by avalanching (e.g. areas mapped as HC1A in Forty Mile Creek valley in Banff) and by recent fire (e.g. areas mapped as HC1B in Molar Creek valley in Banff) occur infrequently.

Discussion

The HC1 Ecosite is broad in concept and encompasses wet fluvial terrain dominated by closed to open spruce forest in the Lower Subalpine. The Vermilion Lakes 3 and 4 (VL3, VL4) Ecosites resemble and are the Montane counterparts of HC1 but have different v.t.s, relating to the Ecoregion in which they occur. There is no Upper Subalpine counterpart of HC1. The wet segments of the Baker Creek 1, 4, and 6 (BK1, BK4, BK6), Cavell 1 (CA1), Consolation Valley 1 (CV1), Topaz 2 (TZ2), and Merlin Castle 1 (MC1) Ecosites sometimes resemble HC1, but are too small to be delineated as HC1 at a mapping scale of 1:50,000. Also, conceptually these Ecosites have a compound dry > wet or wet > dry landscape pattern and different landforms with attendant differences in soil and vegetation which serve to distinguish them from HC1. The HC4 Ecosite is differentiated from HC1 by its shrub dominated vegetation. The HC2 Ecosite is differentiated by its active fluviolacustrine deposition influencing soil and vegetation (Table 200).

HC2 - HECTOR 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite HC2 is characterized by wet fluviolacustrine floodplains dominated by sedge fen vegetation. These level floodplains consist of calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) and are associated with glacial streams near the Continental Divide in Banff and Jasper. The floodplain surfaces are usually eroded (channeled). Pools, ponds, and small lakes are abundant on some HC2 tracts.

Very poorly drained Rego Gleysols lacking organic surface layers are dominant and reflect active accretion by siltation from ponded, silt-laden streams. Vegetation of the HC2 Ecosite also refelcts siltation and is dominated by a bryoid-poor variant of the water sedge-beaked sedge (H11) v.t.

Table 203 Pedon (Alberta 1978 No. 90) description of a Rego Gleysol of the HC2 Ecosite.

Geomorphology

The HC2 Ecosite is typified by level fluviolacustrine floodplains consisting of calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B). Ponding of silt-laden glacial streams on lakehead deltas and behind river channel constrictions (natural dams) promotes aggradation by siltation. The deltaic floodplain at the head of upper Waterfowl Lake in Banff (Plate 11b) is an example of delta-like HC2 tracts. Other examples are the gravelly fluvial fans of the upper North Saskatchewan River (a PP4+SC tract) and Rampart Creed (a PP3 tract) that have constricted flow of the Alexandra and North Saskatchewan Rivers in Banff, respectively, to the extent that backwater floodplains have been formed upstream from the constrictions (Smith 1972). Areas mapped as HC2 are exemplified by these documented channel constrictions which provide a geomorphic setting for the deposition of fluviolacustrine silts and clays with incorporated organic material occurring as thin, fibrous, silt- and clay-laden layers and pockets. Depth of fluviolacustrine plus organic material is unknown, although Smith (1972) reports up to 7.5 m of material. Underlying material is probably glaciofluvial gravels and sands on constricted river floodplains, glaciolacustrine clays and silts on lakehead deltas. A few small lakes have been filled in by fluvial and fluviolacustrine materials. The very poorly drained portion of what was once a small lake, in the tributary valley immediately north of Peyto Lake in Banff, provides the geomorphic setting for a tract mapped as HC2.

Topographically, HC2 displays linear slopes ranging from 0 to 1%. Slope continuity is broken by numerous active stream channels meandering across the landscape. These channels contain the numerous distributaries of the main stream. Narrow, slightly elevated levees frequently border the channels. Excepting the levees, HC2 is usually inundated with water. Pools, ponds, and small lakes are abundant on some HC2 tracts.

Soils

Rego Gleysols dominate the HC2 Ecosite. These very poorly drained soils reflect ponding and active siltation. Prolonged periods of saturation plus active aggradation inhibit soil development other than strong mottling and gleying. Soils of the HC2 Ecosite lack the surface organic layers (peaty phases) common to soils of other wet Ecosites. On a few tracts (e.g. Dolomite Creek valley in Banff) Rego Gleysols with thin, calcareous, silt-bearing, organic horizons at the surface indicate that the inundating waters do not have a heavy sediment load. These features are transitional to HC4. A pedon illustrating Rego Gleysols of HC2 is described in Table 203 and shown in Plate 119. The sample site and vegetation are shown in Plates 120 and 121.

Vegetation

A bryoid-poor variant of the water sedge-beaked sedge (H11) v.t. dominates HC2 and reflects active siltation from silt-laden glacial meltwater. *Carex physocarpa* is often dominant or codominant with *Carex aquatilis* and *Carex rostrata* on this H11 variant. *Salix brachycarpa* occurs frequently but with low cover. Moss cover is low. Willow/horsetail (S7) occurs as an accessory v.t. on the natural levees bordering distributary streams. Sedge-saxifrage (H3) occurs in small amounts on stream channel borders. Unvegetated portions may occur and account for 50% or more of tracts mapped as HC2+SC (e.g. Dolomite Creek in Banff). A vegetation plot illustrating the bryoid-poor variant of H11 on HC2 is presented in Table 204.

Discussion

The HC2 Ecosite is the least extensive of the Hector Ecosites and, overall, is of small areal extent. It encompasses inundated, actively aggrading, fluviolacustrine floodplains with sedge fen vegetation, features that differentiate it from HC1 and HC4 (Table 200). The Vermilion Lakes 1 (VL1) and Num-Ti-Jah (NT3) Ecosites are the Montane and Upper Subalpine counterparts, respective-

ly, of HC2. Further, VL1 and NT3 occur on fluviolacustrine landforms but include geomorphically inactive floodplains where organic materials are accumulating on the surface. Consequently, VL1 and NT3 have Organic soils besides the Rego Gleysols.

HC4 - HECTOR 4 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, HC4, encompasses wet fluvial landforms dominated by shrubby vegetation. These landforms consist primarily of calcareous, coarse, stratified fluvial material (Fluvial material B), occasionally of noncalcareous, coarse, stratified fluvial material (Fluvial material A). Surface expressions include level floodplains, aprons, and fans. Many surfaces are eroded (channeled). The subdominant landform consists of horizontal fens that thinly mantle the fluvial materials on ponded localities.

A complex set of genetically related soils, reflecting recently deposited parent material and varying degrees of gleying, saturation, and organic matter accumulation, characterizes the HC4 Ecosite. These soils are best represented by a soil pattern in which Rego Gleysols are dominant and Gleyed Cumulic Regosols and Terric Mesisols are subdominant. Vegetation is also complex and is best represented by the dwarf birch-shrubby cinquefoil-willow/brown moss (S1), dwarf birch-shrubby cinquefoil/needlerush (S3), willow/timber oatgrass (S11), and water sedge-beaked sedge (H11) v.t.s. The S1 v.t. is most abundant.

Geomorphology

The HC4 Ecosite is typified by fluvial landforms consisting primarily of calcareous, coarse, stratified fluvial material (Fluvial material B). A few tracts are dominated by noncalcareous, coarse, stratified fluvial material (Fluvial material A). Weakly calcareous mixtures of the two fluvial deposits occur often. Calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) occurs on tracts associated with glacial streams (e.g. along the Glacier River in Banff). Important accessory genetic materials, occurring as veneers on or as layers within the fluvial deposits, are calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) and, occasionally, altered, fine, stratified gluviolscustrine material (Fluviolacustrine material A). The fluviolacustrine materials occur on what were backwater depositional localities of floodplains and as veneers on the fringes of aprons and fans. Organic soils frequently overlie fluviolacustrine material, both features indicating ponding by currentless, relatively stagnant water. The fluvial and fluviolacustrine deposits may contain reworked material originally deposited as altered, medium textured eolian material (Eolian material B). Various tills underlie the fluvial deposits at shallow depths on some localities.

Ecosites mapped as HC4 are usually mantled by thin peat deposits derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat, rarely exceeding 1.2 m in thickness, is mainly moderately decomposed but fibric and humic layers also occur. Occasionally wood fragments may be found. Where the peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b). The fen peat is underlain, within the control section, by the fluvial and fluviolacustrine deposits. On some sites Eolian material B containing volcanic ash is preserved in thin layers at or near the base of organic deposits.

Topographically, HC4 displays gentle linear slopes on level floodplains, aprons, and fans. Slopes commonly range from 0 to 9%. Tracts with complex slopes have irregular surfaces reflecting, in part, underlying morainal landforms. Slope continuity is often broken by abandoned and active stream channels including their natural levee borders. Weakly expressed terracing (risers <1 m) is a minor feature on some floodplain tracts.

Soils

Soils of the HC4 Ecosite are complex and reflect recently deposited parent material and varying degrees of gleying, saturation, and organic matter accumulation. These imperfectly, poorly, and very poorly drained soils are best represented by a pattern in which Rego Gleysols are dominant and Gleyed Cumulic Regosols and Terric Mesisols are subdominant. Strength of gleying is variable and reflects degrees of water table fluctuation, lateral water movement, and seepage water aeration. Prolonged periods of saturation produce strongly gleyed soils with little or no pedogenic horizonation (Rego Gleysols). Gleyed Cumulic Regosols and the accessory soils, Gleyed Regosols, Gleyed Eutric Brunisols and Orthic Gleysols, occur where saturation periods are shorter and the depth to the water table is greater. Pedogenic horizonation in the Regosolic soils is limited by active or recently active fluvial deposition. The Gleyed Eutric Brunisols and Orthic Gleysols occur on the oldest surfaces where sufficient time for B horizon development has elapsed. Favorable moisture, nutrient, and vegetation conditions have resulted in the accumulation of varying thicknesses of fen peat on most HC4 soils. Terric Mesisols occur where the peat is >40 cm thick. Other soils with subdominant humic or fibric layers and Humic Gleysols occur occasionally. Well to moder-

ately well drained Brunisolic and Regosolic soils occupy sites where the fluctuating water table is generally below the control section.

A pedon illustrating Rego Gleysols of HC4 is described in Table 205 and shown in Color Plate 27. The top two horizons of this pedon occur in Fluviolacustrine material B. A pedon illustrating Terric Mesisols of HC4 is described in Table 206 and shown in Color Plate 28. The low lime mineral material in this profile (Cg2 and Cg3 horizons) is Fluviolacustrine material A derived from erosion of the quartzite dominated slopes above the floodplain. Because the tract is part of the Sunwapta River floodplain, calcareous Fluviolacustrine material B and Fluvial material B is expected deeper in the profile.

Vegetation

Vegetation of the HC4 Ecosite is complex and is best represented by the dwarf birch-shrubby cinquefoil-willow/brown moss (S1), dwarf birch-shrubby cinquefoil/needle-rush (S3), willow/timber oatgrass (S11), and water sedge-beaked sedge (H11) v.t.s. The most abundant v.t. is S1 but some tracts may be dominated by S3 and S11. Occasionally, H11 may be codominant with the shrubby vegetation. The H11 v.t. occurs mostly in ponded localities, often with Organic (Terric Mesisols) soils. Willow-dwarf birch/fleabane (S4), willow/cinquefoil (S8), dwarf birch-willow/kobresia (S9), and sedge-saxifrage (H3) are important accessory v.t.s on HC4. The S4 and S8 v.t.s. are more common at high elevations and may reflect cold air drainage on valley bottom positions. On HC4, S8 and S11 display a wide range of moisture tolerances, occurring on well drained to poorly drained sites. The S11 v.t. is often associated with Gleyed Cumulic Regosols on imperfectly drained sites. The water table probably fluctuates upwards

into the control section only a few times during the growing season on these better drained sites. The H3 v.t. occurs mostly on active stream channel margins where flooding and deposition occur frequently. The willow/horsetail (S7), willow-dwarf birch-shrubby cinquefoil (S10), willow/hairy wild rye (S12), yellow dryad-willow herb (H8), white spruce/shrubby cinquefoil/bearberry (O3), and Engelmann spruce-subalpine fir/willow/ribbed bog moss (O6) v.t.s occur in minor amounts on HC4. Actively aggrading and eroding stream reaches lacking vegetation occupy up to 50% of some tracts. Tracts mapped as HC4+SC have 50 to 80% unvegetated portions. Modification of HC4 vegetation by avalanching, mapped as HC4A, occurs infrequently.

A plot representing vegetation of the Rego Gleysol pedon sample site described above (Table 205) and illustrating S1 on HC4 is presented in Table 207 and Plate 50. A plot representing the vegetation of the Terric Mesisol sample site (Table 206) and illustrating S3 on wetter areas of HC4 is presented in Table 208 and shown in Plate 122.

Discussion

The HC4 Ecosite is broad in concept and encompasses wet fluvial terrain dominated by shrubby vegetation in the Lower Subalpine. The Vermilion Lakes 5 (VL5) and Num-Ti-Jah 2 (NT2) Ecosites are the Montane and Upper Subalpine counterparts, respectively, of HC4. Further, the vegetation and soils of NT2 reflect the higher elevations of the Upper Subalpine and slightly drier conditions than on HC4. The wet segments of the Baker Creek 1, 4, and 6 (BK1, BK4, BK6), Cavell 1 (CA1), Consolation Valley 1 (CV1), Topaz (TZ2), and Merlin Castle 1 (MC1) Ecosites sometimes resemble HC4 but are too small to be delineated as HC4 at a mapping scale of 1:50,000. Also, conceptually, these Ecosites have a dry > wet or wet > dry landscape pattern and different landforms with attendant differences in soil and vegetation which distinguishes them from HC4. The HC1 Ecosite is differentiated from HC4 by its closed to open forest dominated vegetation. The HC2 Ecosite is differentiated by its active fluviolacustrine deposition influencing soil and vegetation (Table 200).

HD - HILLSDALE ECOSECTION

The Hillsdale (HD) Ecosection encompasses fluvial landforms (fans, aprons, and floodplains) comprised of calcareous, coarse, stratified fluvial material (Fluvial material B)

throughout the Montane Ecoregion in Banff and Jasper. Channeling (Eroded modifier, C.S.S.C. 1978b) is a common surface feature. Regosolic soils associated with aspen forest, white spruce open and closed forest, white spruce-Douglas fir forest, and grassland > lodgepole pine forest characterize HD.

The HD Ecosection is widely distributed, occurring on lower slopes and valley floors of the Bow and North Saskatchewan River and Lake Minnewanka valleys in Banff. In Jasper, it occurs along the Athabasca, Miette, Whirlpool, Maligne, Snake Indian, Rocky River, and Moosehorn Creek valleys.

Four Ecosites are recognized within the HD Ecosection and are separated primarily on vegetation differences. Table 209 outlines the general features of the HD Ecosection. Representation of HD2 on the landscape is presented in Figure 47 and representation of HD3 is presented in Figure 38. The HD1 and HD4 Ecosites occupy similar landscape positions.

HD1 - HILLSDALE 1 ECOSITE

Ecosite Concept

The Montane Ecosite, HD1, encompasses fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Surfaces are usually channelled. The soil component is dominated by Orthic and Cumulic Regosols. Vegetation is dominated by the aspen/hairy wild rye-peavine (C16) v.t. The HD1 Ecosite occurs throughout the Montane in Banff and Jasper.

Geomorphology

The HD1 Ecosite is typified by fluvial fans, aprons, and occasionally floodplains consisting of calcareous, coarse, stratified fluvial material (Fluvial material B). Irregular surfaces produced by channeling are common features. Landforms characterizing HD1 consist of materials eroded from the morainal, colluvial and rock slopes occurring above them. Stratified deposits, including interbedded and mixed humus, are manifestations of episodic fluvial deposition. Tracts of HD1 in Jasper north of Jasper Lake in the Athabasca River valley, are overlain by veneers of calcareous, medium textured eolian material (Eolian material A). Some of these deposits may have been reworked by water, making them fluvioeolian deposits. Tracts of HD1 in the Miette River valley and below Pyramid Mountain in Jasper are comprised of noncalcareous, coarse, stratified fluvial material (Fluvial material A). The absence of lime on these tracts is controlled by the surrounding noncalcareous bedrock.

Topographically, HD1 displays linear slopes on fans and aprons. Slopes commonly range from 1 to 15% with the gentler slopes confined to apron and fan toes on valley floors and to minor amounts of level floodplains. Slope continuity is often broken by abandoned and active stream channels including their natural levee margins (Eroded modifier, C.S.S.C. 1978b).

Soils

Soils of the HD1 Ecosite are well drained and reflect relatively recent deposits and periodic depositional activity. Orthic and Cumulic Regosols are dominant. Orthic Eutric Brunisols are accessory soils that occupy slightly elevated portions of the landscape that are rarely flooded. Minor amounts of moderately well drained and gleyed soils occur near the toes of fans and aprons that are seasonally affected by fluctuating water tables. A pedon illustrating Cumulic Regosols of HD1 is described in Table 210 This pedon was sampled on the Carrot Creek fan in Banff.

Vegetation

Vegetation cover on HD1 is dominated by the aspen/hairy wild rye-peavine (C16) v.t. Balsam poplar/buffaloberry (C17) is an accessory v.t. that primarily occurs on portions of HD1 affected by fluctuating water tables. Lodgepole pine and white spruce dominated v.t.s are often mixed with C16 on portions of

Discussion

Portions of fluvial landscapes in the Montane Ecoregion with the aspen/hairy wild rye-peavine (C16) v.t. may resemble but not be mapped as HD1. This happens because their areal extent is too small to be delineated at a 1:50,000 map scale. They thus occur in minor amounts in other Ecosites. The Pipestone 2 (PP2) Ecosite is the Lower Subalpine counterpart of HD1. The HD1 Ecosite is separated from other HD Ecosites primarily on vegetation differences as outlined in Table 209.

HD2 - HILLSDALE 2 ECOSITE

Ecosite Concept

The Montane Ecosite, HD2, encompasses fluvial fans, aprons, and floodplains comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Surfaces are usually channeled. The soil component is dominated by Orthic and Cumulic Regosols. Vegetation is dominated by the white spruce/shrubby cinquefoil/bearberry (O3) v.t.

In Jasper, the majority of HD2 tracts occur along the Athabasca River valley north of the Snaring River to Jasper's East Gate. In Banff, HD2 tracts occur throughout the Montane in the Bow and North Saskatchewan River valleys.

Geomorphology

The HD2 Ecosite is typified by fluvial fans, aprons, and level floodplains consisting of calcareous, coarse, stratified fluvial material (Fluvial material B). Irregular surfaces produced by channelling are common features. Stratified deposits, including interbedded and mixed humus, are manifestations of episodic fluvial deposition. In Jasper, HD2 tracts north of Jasper Lake in the Athabasca River valley are overlain by veneers of calcareous, medium textured eolian material (Eolian material A). Some of these deposits have been reworked by water, making them fluvioeolian deposits.

Topographically, HD2 is characterized by linear slopes on fans and aprons. Slopes commonly range from 1 to 15% with the gentler slopes confined to fan and apron toes, and level floodplains on valley floors. Slope continuity is often broken by abandoned and active stream channels including their natural levee margins.

Soils

Soils of the HD2 Ecosite are well to moderately well drained and reflect relatively young deposits and periodic depositional activity. Orthic and Cumulic Regosols are dominant. Minor amounts of Gleyed Cumulic Regosols occur on imperfectly drained sites that are seasonally affected by fluctuating water tables. These soils are commonly found on the wetter portions of eroded (channeled) floodplains and the toes of fluvial fans and aprons. A pedon illustrating Cumulic Regosols of HD2 is described in Table 212. This pedon was sampled on the Rocky River fan in Jasper. The upper 74 cm of this pedon is possibly a veneer of calcareous, medium textured eolian material (Eolian material A).

Table 212 Pedon (Alberta 1978 No. 18) description of a Cumulic Regosol of the HD 2 Ecosite.

Discussion

The HD2 Ecosite may resemble portions of the Vermilion Lakes 3 (VL3) Ecosite where the O3 v.t. occurs. However, VL3 is generally on poorly drained floodplains, whereas HD2 occurs on moderately well drained fans. The Pipestone 6 (PP6) Ecosite is the Lower Subalpine counterpart of HD2. The HD2 Ecosite is separated from other HD Ecosites primarily on vegetation differences as outlined in Table 209.

HD3 - HILLSDALE 3 ECOSITE

Ecosite Concept

The Montane Ecosite, HD3, encompasses fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Surfaces are usually channeled. The soil component is dominated by Orthic and Cumulic Regosols. Vegetation is dominated by the white spruce/fern moss (C2), white spruce/prickly rose/fern moss (C27), white spruce-Douglas fir/feathermoss (C5) and white spruce/buffaloberry/fern moss (C26) v.t.s. The most abundant v.t.s are C2 and C27. The HD3 Ecosite is found throughout the Montane in both parks.

Geomorphology

The HD3 Ecosite occurs on fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Irregular surfaces produced by channeling are common features. Stratified deposits, including interbedded and admixed humus, are manifestations of episodic fluvial deposition. In Jasper, HD3 tracts in the Athabasca River valley north of Jasper Lake are overlain by calcareous, medium textured eolian material (Eolian material A). Some of these deposits have been reworked by water, making them fluvioeolian deposits. Tracts mapped as HD3 in the Miette River valley in Jasper are comprised of noncalcareous, coarse, stratified fluvial material (Fluvial material A).

Topographically, HD3 displays linear slopes on fans and aprons. Slopes commonly range from 1 to 15% with gentler slopes confined to apron and fan toes on valley floors and to a minor proportion of level floodplains and fluvial terraces. Slope continuity is often broken by abandoned and active stream channels including their natural levee margins.

Soils

Soils of the HD3 Ecosite are well to moderately well drained and reflect relatively young deposits and periodic depositional activity. Orthic and Cumulic Regosols are dominant. Orthic Eutric Brunisols are accessory soils that occupy slightly elevated portions of the landscape that are rarely flooded. Minor amounts of gleyed soils occur near the toes of fans and aprons that are seasonally affected by fluctuating water tables. A pedon

Table 214 Pedon (Alberta 197[illegible] No. 99) description of a Cumulic Regosol of the HD3 Ecosite.

CLASSIFICATION: TAXONOMIC SYSTEM OF THE YEAR 1978, SUBGROUP: CUMULIC REGOSOL. SOIL MAP UNIT: NOTATION: HD3.

illustrating Cumulic Regosols of the HD3 Ecosite is described in Table 214 and shown in Color Plate 29. This pedon was sampled above the Bow River southeast of the golf course in Banff.

Vegetation

The HD3 Ecosite is dominated by the white spruce/fern moss (C2), white spruce/prickly rose/fern moss (C27), with lesser amounts of white spruce-Douglas fir/feathermoss (C5), and white spruce/buffaloberry/fern moss (C26) v.t.s. A few HD3 tracts are dominated by C5 or C26. The C2, C26 and C27 v.t.s are generally associated with veneers of calcareous, medium textured eolian material (Eolian material A) along the North Saskatchewan River valley in Banff and the Athabasca River valley north of Jasper townsite. Also, C26 occurs on the Snake Indian River floodplain below the Seldom Inn warden cabin in Jasper. The calciphile, *Thuidium abietinum*, is the predominant moss in the understory of the above v.t.s and usually occurs on calcareous materials. In Banff, C5 is more abundant than in Jasper, commonly occurring on northerly aspects. A stand illustrating the C5 v.t. on HD3 is described in Table 215 and shown in Plate 124 and represents vegetation at the pedon sample site described above in Table 214.

Discussion

The Pipestone 3 (PP3) Ecosite is the Lower Subalpine counterpart of HD3. The HD3 Ecosite is separated from the other HD Ecosites primarily on vegetation differences as outlined in Table 209.

HD4 - HILLSDALE 4 ECOSITE

Ecosite Concept

The Montane Ecosite, HD4, encompasses fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Surfaces are usually channeled. Orthic and Cumulic Regosols are the dominant soils associated with a pattern of vegetation dominated by the junegrass-pasture sage-wild blue flax (H6) v.t. and a lesser percentage of the lodgepole pine/juniper/bearberry (C3) v.t.

In Jasper, HD4 tracts primarily occur in the Athabasca River valley between Jasper townsite and Jasper's East Gate. In Banff two tracts of HD4 occur, one at Hillsdale and the other in the vicinity of the Banff airport.

Geomorphology

The HD4 Ecosite encompasses fluvial fans and aprons comprised of calcareous, coarse, stratified fluvial material (Fluvial material B). Irregular surfaces produced by channeling are common features. Stratified deposits, including interbedded and mixed humus, are manifestations of episodic fluvial deposition. In Jasper, HD4 tracts north of Jasper Lake in the Athabasca River valley are overlain by veneers of calcareous, medium textured eolian material (Eolian material A). Some of these deposits have been reworked by water, making them fluvioeolian deposits.

Topographically, HD4 displays linear slopes on fans and aprons. Slopes commonly range from 1 to 15% with gentler slopes confined to fan and apron toes on valley floors. Slope continuity is often broken by abandoned and active stream channels including their natural levee margins.

Soils

Soils of the HD4 Ecosite are rapidly to well drained and reflect relatively recent deposits and periodic depositional activity. Orthic and Cumulic Regosols are dominant. Orthic Eutric Brunisols occur in minor amounts on slightly elevated portions of the landscape that are rarely flooded. Organically enriched (Ah) horizons develop under grassland on HD4 tracts affected by veneers of calcareous, medium textured eolian material (Eolian material A), resulting in minor amounts of Orthic and Cumulic Humic Regosols. A pedon illustrating Cumulic Regosols of HD4 is described in Table 216 and shown in Color Plate 30. This pedon was sampled between Edith Lake and the confluence of the Maligne and Athabasca Rivers in Jasper. This pedon has horizons with organic matter contents that vary irregularly with depth, making it a Cumulic Regosol.

Vegetation

The vegetation pattern of HD4 is dominated by the junegrass-pasture sage-wild blue flax (H6) v.t., with a lesser abundance of the lodgepole pine/juniper/bearberry (C3) v.t. Historically, fire has had a major effect on HD4 tracts. In Jasper, the addition of calcareous, medium textured eolian material (Eolian material A) is also a factor contributing to the vegetation assemblage. Minor amounts of the white spruce/juniper/bearberry (O17) and white spruce/shrubby cinquefoil/ bearberry (O3) v.t.s occupy localities where eolian material is still actively aggrading. A plot illustrating the H6 v.t. of HD4 is described in Table 217 and shown in Plate 125 and represents the vegetation at the pedon sample site described above in Table 216.

Discussion

The HD4 Ecosite is the least extensive of the HD Ecosites. Presently, there exists a tension between grassland and forest on HD4 tracts. Forest encroachment of the grassland is slowly reducing its acreage. Evidence of this hypothesis is given in the discussion section of the Athabasca 3 (AT3) Ecosite. In terms of landform surface expression, soils, and vegetation cover, HD4 most resembles the AT3 Ecosite. They also have similar eolian veneers but AT3 occurs on terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) whereas HD4 occurs on fluvial fans. The HD4 Ecosite is separated from other HD Ecosites primarily on vegetation differences as outlined in Table 209.

HE - HEATHER ECOSECTION

The HE Ecosection occurs on either rock (consolidated) or residuum (unconsolidated bedrock) in the Alpine Ecoregion. Lithic phases of Brunisolic and Regosolic soils dominate areas where soil exists, but areas of nonsoil (surface veneers <10 cm thick over bedrock) are common. Mountain avens tundra vegetation mantles most areas except the unvegetated bedrock outcrops, where vegetation is extremely sparse.

The HE Ecosection occurs at high elevations throughout Banff and Jasper, with distribution and extent controlled by bedrock structure, lithology, and surface topography. Examples are mapped north of Mount Eisenhower in Banff and on the De Smet Range in Jasper. Two Ecosites (HE1, HE2) are recognized, with separation based on the occurrence and nature of consolidated versus unconsolidated bedrock and the resultant effects on soil and vegetation as outlined in Table 218.

HE1 - HEATHER 1 ECOSITE

Ecosite Concept

The HE1 Ecosite occurs on both noncalcareous, medium textured residuum (Residuum A) and calcareous, medium textured residuum (Residuum B) veneers over inclined, hummocky, and ridged bedrock in the Alpine ecoregion. Soils are lithic and often include turbic phases of Orthic Sombric Brunisols, Orthic Melanic Brunisols, and Orthic Humic Regosols. Vegetation is dominantly the mountain avens-snow willow-moss campion (H1) v.t.

The HE1 Ecosite occupies high plateaus, broad passes and rounded mountain peaks and ridges underlain by recessive, highly jointed, medium and fine grained clastic rocks, both calcareous and noncalcareous.

The HE1 Ecosite is distributed sporadically throughout both Banff and Jasper. An extensive example mantling the De Smet Range in Jasper is shown in Plate 126.

Table 218 General features of the heather (HE) Ecosites.

Ecosite	Landform	Soils	Vegetation
HE1	Residuum A,B; inclined, hummocky, ridged	lithic phases of Brunisols and Regosols	mountain avens tundra
HE2	Calcareous bedrock; ridged > calcareous regolith veneer over rock	Nonsoil >> lithic phases of Brunisols and Regosols	Unvegetated > mountain avens tundra

Geomorphology

The HE1 Ecosite occurs on both noncalcareous, medium textured residuum (Residuum A) and calcareous, medium textured residuum (Residuum B) in the Alpine Ecoregion. These genetic materials occupy complex slopes of up to 45%, and occur as veneers over the inclined, hummocky, or ridged bedrock from which they were derived. Steeper slopes on HE1 are frequently soliflucted, producing a variant of colluvial material that resembles the original residuum. On exposed positions, some gentler slopes show evidence of either active or inactive cryoturbation.

This Ecosite occurs in two different topographic situations that have different genetic material histories. Occasionally, tracts occupy high, broad plateaus and passes. These areas generally have been glaciated, and till occurs locally or is mixed with the residuum. More frequently HE1 is mapped on higher, rounded mountain peaks and ridges that show little evidence of, or may have escaped, glaciation (Stalker 1973, Harrison 1976). These surfaces may be much older than the lower, glaciated ones.

In both instances, residuum (soil parent material) was produced by both physical and weak chemical weathering of highly jointed, medium and fine grained recessive rock. Frost activity along jointing (joint-block separation) resulted in a much greater surface area exposed to weathering of the cement holding the grains of the rock together. These processes are still active on HE1. Failed bedrock accounts for only a few tracts of HE1.

A strong relationship exists between the nature of the underlying bedrock and the physical and chemical characteristics of the resulting residuum. In the Main Ranges, HE1 occurs nearly exclusively on Residuum A derived from Miette Group strata. Mesozoic strata in the Front Ranges generally produce either Residuum B on the Triassic aged Spray River Group, or Residuum A on Jurassic and Lower Cretaceous bedrock. Tracts of greatest extent and uniformity occur where bedding planes of in situ, residuum-producing bedrock conform closely to the ground surface (Plate 126). Irregular surfaces cutting across differing strata produce small tracts with locally diverse characteristics, often including both Residuum A and Residuum B.

Intact eolian veneers are not common on HE1 but the material may often have been incorporated into the residuum by cryoturbation or solifluction. On exposed sites these processes occasionally produce bare mineral soil that is subject to deflation.

Soils

Soils occurring on HE1 are taxonomically diverse with lithic phases of Orthic Sombric Brunisols, Orthic Melanic Brunisols, and Orthic Humic Regosols among the most common. Thick, dark colored Ah horizons high in organic matter are common to these soils. Other soils of HE1, Orthic Dystric Brunisols, Orthic Eutric Brunisols, and Orthic Regosols, are similar respectively to the Ecosite concept soils listed above but have thinner Ah horizons. Turbic phases of soils are common with both cryoturbation and solifluction (processes often responsible for the Regosolic soils). Sombric and Dystric Brunisols are associated with Residuum A while Melanic and Eutric Brunisols occur on Residuum B. A pedon from Pipestone Pass in Banff sampled to represent soils of HE1 is presented in Table 219, and shown in Color Plate 31. Plate 127 shows this sample site.

This pedon is an Orthic Dystric Brunisol, lithic and turbic phases, and the variable depth (6-12 cm) of the Ah horizon indicates it intergrades to Orthic Sombric Brunisol soils. It has developed in an Eolian material B veneer deposited over Residuum A which was derived from a pebble conglomerate bed within the Miette Group strata, rather than from the more typical slates and shales. The Bhfy horizon probably contains some altered, medium textured eolian material (Eolian material B). This same horizon has a high organic carbon content.

Other soils may occur in the mosaic. More extreme cryoturbation or solifluction may produce turbic phases of Cumulic Regosols. Podzolic B horizons occur occasionally, especially on stable sites in western Banff and southwestern Jasper where Eolian material B is incorporated into the solum. Areas of nonsoil occur on upper slopes and on irregular surfaces with varying lithology.

Soils are well drained in general but depressions in the bedrock surface can trap water, causing poor drainage locally. These areas often have pronounced frost hummocks. In spring, even the well drained soils are often temporarily saturated above the frost table and are unstable until further thaw allows internal drainage to remove excess water.

Vegetation

Vegetation is most commonly the mountain avens-snow willow-moss campion (H1) v.t. It by far dominates HE1 tracts on the eastern

side of the parks. Toward the Continental Divide H1 still is prevalent but areas of white mountain heather-mountain avens-snow willow (L4) and heather-everlasting (L5) become common. A vegetation plot sampled within 1 km of the pedon described in Table 219 and occurring on similar residuum and the same soil Subgroup and phase is presented in Table 220. This plot occurs in a landscape similar to the above pedon sample site shown in Plate 127. It is classified as an L4 v.t. which is an accessory v.t. on HE1. This L4 v.t. plot represents a moderately deep snowbed community and occurs in a mosaic with the H1 v.t. that occurs on more exposed shallower snow sites.

Table 220 Stand (PA7119) illustrating white mountain heather-mountain avens-snow willow (L4), an accessory v.t. of the HE1 Ecosite.

VALUES ARE PERCENT COVER EXCEPT FOR EPIPHYTES WHERE 0.5 INDICATES THE SPECIES WAS PRESENT.

Other v.t.s occurring less commonly include black alpine sedge-everlasting (H2) on moist, deep snowbed sites close to the Continental Divide and arctic willow-cinquefoil (L7) on moist, moderately deep snowbed sites. Sparcely vegetated (<20% cover) portions occur in severely cryoturbated and soliflucted areas on turbic Regosolic soils. Saxicolous lichen (H12) occurs at high elevations, especially on noncalcareous, medium textured residuum (Residuum A) and also on areas of nonsoil.

Discussion

Because of the diversity encompassed by HE1, it resembles most other Alpine Ecosites in some respects. Steeper soliflucted slopes on Residuum A resemble the colluvial Redoubt 1 (RD1) while on Residuum B they resemble the colluvial Bow Summit 1 (BS1). The colluvial deposits are usually deeper over bedrock than HE1, especially on lower slopes, and form steeper, more linear slopes than HE1. Quartzite and quartz sandstone is not highly jointed in the parks, so noncalcareous, coarse textured residuum resembling the colluvium of Tekarra 1 (TK1) seldom develops. Residuum A tracts mapped as HE1 resemble Jonas 1 with thin till and dominantly lithic soils (JN1X) but are distinguished by the residual versus till genetic materials. Similarly, HE1 on Residuum B resembles Molar Pass 1 on tracts with thin till and lithic soils (MP1X). The HE1 Ecosite, with noncalcareous, coarse textured residuum resembling the till of Eiffel 1 (EF1X tracts) does not commonly develop. The HE1 Ecosite is the Alpine counterpart of the Upper Subalpine Ecosite Copper 1 (CP1). Also, CP1 usually only occurs on Residuum A found on failed bedrock. The HE2 Ecosite occurs in a different structural, stratigraphic and topographic setting than HE1. Ecosite characteristics of each are outlined in Table 218.

The HE1 Ecosite makes up a greater percentage of the vegetated Alpine Ecoregion than its residual counterparts do in lower Ecoregions because glaciation stripped away most pre-existing residuum in the Subalpine and Montane.

HE2 - HEATHER 2 ECOSITE

Ecosite Concept

The Alpine Ecosite, HE2, occurs dominantly as ridged bedrock outcrops with a mosaic of thin surficial veneers. Because of the extensive outcrops, most areas are nonsoil (<10 cm of unconsolidated material over bedrock) and unvegetated (scattered vegetation, with cover <20%). Where soils occur, they are lithic phases of Orthic Melanic Brunisols and Orthic Humic Regosols. Vegetation is more extensive than soil, as it develops on both soil and nonsoil areas and is most frequently identified as the mountain avens-snow willow-moss campion (H1) v.t.

Heather 2 occurs at high elevations on cirque floors that are generally carved into resistant carbonate strata of the upper stratigraphic column of the Main Ranges. Thus, this Ecosite is mainly distributed in the central to western side of the parks. Extensive examples are mapped just north of Mount Eisenhower in Banff, and one of these is shown from a distance of a few kilometres in Plate 128.

Geomorphology

The HE2 Ecosite occurs on ridged bedrock outcrops with a sporadic regolith veneer. This regolith is a mosaic of eolian, morainal, fluvial, colluvial, and residual materials or mixtures thereof.

Bedrock controls many of the characteristics of HE2. Most tracts occur on calcareous strata of the upper stratigraphic column of the Main Ranges in central and western Banff and Jasper (Fig. 4). Outcrop lithology is dominantly dense, massive, resistant limestone and dolomitic limestone of early to middle Cambrian age. Geologically associated units are the Lynx Group, and the Cathedral and Eldon Formations. Occasionally, other Paleozoics with massive carbonate members, such as the Palliser Formation, underlie HE2. Surfaces of this Ecosite often closely parallel the characteristically gently dipping bedding planes of these Main Ranges Formations (Plate 128). Slopes are commonly 5 to 30% complex. Where the ground surface cuts across steeply dipping bedding planes of varying lithology, more rugged landscapes with complex slopes between 30 and 70% occur (Plate 129). Bedrock is the dominant feature of HE2. The dense, massive, carbonate bedrock in the Main Ranges structural setting is less affected by deformation and jointing than most other rocks in the parks. Thus, the scouring agents of glaciation removed and carried away less resistant overlying rock, leaving roughly planar (bedding planes), debris-free surfaces. The HE2 Ecosite is often found in hanging cirques because of this resistant rock (Plate 128). Sporadic veneers of calcareous, medium textured till (Till C) are the only vestige of glacial debris, indicating that in their later stages, glaciers were eroding very little of the resistant underlying bedrock. Widely spaced jointing is not conducive to physical weathering while chemical weathering is slow on the carbonates as evidenced by fresh surfaces with still visible glacial striations in areas where the ice front retreated several thousands of years ago. Therefore, calcareous, medium textured residuum (Residuum B) is not abundant. Local veneers of calcareous, medium textured colluvium (Colluvium C) occur on steeper slopes. Runoff water often accumulates on the impermeable bedrock surface and calcareous, coarse, stratified fluvial material (Fluvial material B) is deposited on stream courses. Finally, thin accumulations of altered, medium textured eolian material (Eolian material B) occur in areas protected from erosion. All of these sporadic veneers can be affected by cryoturbation, and on steeper slopes, by solifluction. Occasionally, HE2 was also mapped on areas of noncalcareous Gog Group strata, particularly where the massive quartzites resulted in a similar geomorphic process to that described above.

Soils

Bedrock outcrop dominates HE2, so a great majority of the area of any tract is nonsoil. Where soils do occur (>10 cm unconsolidated material), they are lithic phases of Orthic Melanic Brunisols and Orthic Humic Regosols. Thick dark colored Ah horizons, high in organic matter, are common to these soils. Where this depth is less than 10 cm, soils are Orthic Eutric Brunisols and Orthic Regosols, respectively. The Brunisolic soils often have calcareous B horizons, indicating they are similar to the Regosolic soils. Table 221 describes an Orthic Regosol from the head of the valley containing Brazeau Lake in Jasper and illustrates the soils of HE2. The landscape in the vicinity of this pedon is shown in Plate 129.

The residual parent material at this site has been modified by colluviation. Depth of the Ah horizon (8 cm) indicates that this Orthic Regosol is intergrading to an Orthic Humic Regosol.

R: 30 CM

Except in local fluvial situations, soils are rapidly to well drained. Fluvial areas are dominantly Rego Gleysols. Turbic phases are common, a result of either cryoturbation or solifluction.

Vegetation

A majority of HE2 is unvegetated (scattered vegetation with <20% cover) because of the dominance of bedrock outcrop. Where vegetation occurs it is usually the mountain avens-snow willow-moss campion (H1) v.t. Table 222 describes an H1 v.t. sampled at the same site as the pedon in Table 221 to illustrate vegetated portions of HE2. The landscape in the vicinity of this plot is shown in Plate 129. Other v.t.s occur to a limited extent. Saxicolous lichen (H12) is the initial colonizer of some areas. Toward the Continental Divide, white mountain heather-mountain avens-snow willow (L4) and heather-everlasting (L5) occurs in sheltered areas that have soil. Poorly drained fluvial sites have a variety of v.t.s including willow/cinquefoil (S8), arctic willow-cinquefoil (L7) and occasionally cottongrass/moss (H10) and water sedge-beaked sedge (H11).

Vegetation is more extensive than soil, as it commonly develops on nonsoil as well as soil areas in HE2.

Discussion

Tracts of HE2 present a barren landscape broken by sporadic patches of tundra vegetation. Though of very limited extent, more lush vegetation is associated with watercourses (Plate 128). Thus, the limiting factors to biomass production onHE2 are soil and water as illustrated by Plate 130. Where these occur together, their significance to the ecology of this Ecosite is greater than their areal extent. Plate 130 illustrates a closeup view of a portion of the HE2 tract in Plate 128. The HE2 Ecosite is distinguished from the Miscellaneous Landscape Rockland (R) by having >20% soil and vegetation cover. The HE1 Ecosite occurs in a different structural, stratigraphic, and topographic setting than HE2. Ecosite characteristics of each are outlined in Table 218.

IB - ISHBEL ECOSECTION

The Ishbel (IB) Ecosection encompasses stabilized, hummocky landslide deposits that are variably textured and are derived from either noncalcareous or calcareous bedrock. It is characterized by Brunisolic and Regosolic soils associated with lodgepole pine forest, coniferous open forest, and Engelmann spruce-subalpine fir forest. The Ecosection occurs on mid to lower slope positions in the Lower Subalpine portion of the Subalpine Ecoregion in both parks.

Vegetation is the main criterion for separating the Ishbel Ecosection into three Ecosites (IB1, IB2 and IB3) as outlined in Table 223. Fig. 32 shows physiographic positions of the IB1, IB2 and IB3 Ecosites in relation to adjacent Ecosites.

Table 223 General features of the Ishbel (IB) Ecosites.

Ecosite	Landform	Soils	Vegetation
IB1	Landslide material; hummocky	Brunisolic	lodgepole pine forest
IB2	Landslide material; hummocky	Regosolic, Brunisolic	coniferous open forest
IB3	Landslide material; hummocky	Brunisolic	Engelmann spruce-subalpine fir forest

IB1 - ISHBEL 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, IB1, occurs on hummocky landslide deposits (Landslide material) that are variably textured and derived from either calcareous or noncalcareous bedrock. The IB1 Ecosite is dominated by well drained Orthic and Eluviated Eutric Brunisols, and Eluviated Dystric Brunisols associated with the lodgepole pine/buffaloberry/grouseberry (C18), lodgepole pine/buffaloberry/twinflower (C19), and lodgepole pine/Labrador tea (C29) v.t.s.

Geomorphology

The IB1 Ecosite encompasses stabilized landslides (Landslide material) with hummocky surface expression. The landslide deposits often overlie inclined morainal and bedrock slopes on valley walls. These postglacial deposits range from medium acid to extremely calcareous in reaction and, texturally, from silt loam to loamy sand. They have a high content of variable sized angular and subangular coarse fragments. Surfaces are very stony and bouldery. Discontinuous veneers of altered, medium textured eolian material (Eolian material B) that may significantly increase the surficial fine earth fraction occur on some tracts, especially in western Banff and southwestern Jasper. Surfaces are dominantly irregular with a wide range of complex slopes.

Soils

The IB1 Ecosite is dominated by well drained Orthic and Eluviated Eutric Brunisols, and Eluviated Dystric Brunisols. These soils develop on landslide material that reflects the nature of the bedrock from which it has been derived. Orthic and Eluviated Eutric Brunisols are soils that develop on the calcareous landslides and are primarily medium textured. Eluviated Dystric Brunisols develop on the less common noncalcareous landslide deposits with textures ranging from medium to coarse. These variably textured soils are occasionally fragmental at depth. A pedon described in Table 224 and shown in Color Plate 32 illustrates the soil of the IB1 Ecosite. The Ae and Bm horizons of this pedon are developed in the eolian veneer. The IIBm horizon in this pedon has more clay than the Ae but lacks clay films. This pedon was sampled on a tract of IB1 2.5 km south of Medicine Lake in Jasper.

Vegetation

The IB1 Ecosite is dominated by the lodgepole pine/buffaloberry/grouseberry (C18), lodgepole pine/buffaloberry/twinflower (C19), and lodgepole pine/Labrador tea (C29) v.t.s. The closely related C18 and C19 occur on tracts of IB1 in both parks. The C29 v.t. primarily occurs on IB1 in Jasper. Minor amounts of the Douglas fir/hairy wild rye (C1) v.t. occur near the Montane boundary on a tract of IB1 mapped between Johnston Creek and Hillsdale in Banff. The white spruce/juniper/bearberry (O17) v.t. occurs on tracts of IB1 in patches that are too small to be mapped as Ishbel 2 (IB2). A vegetation plot description in Table 225 and shown in Plate 131 illustrates the C18 v.t. on IB1 and represents the vegetation of the sampled pedon described in Table 224.

Discussion

The IB1 Ecosite is separated from the other Ecosites in the IB Ecosection primarily on vegetational differences as outlined in Table 223. The IB1 Ecosite most resembles the

BZ2 Ecosite in terms of similar surface expression, soils, and vegetation. The BZ2 Ecosite is separated because it has residual genetic material. The IB1 Ecosite may also resemble failed till slopes dominated by lodgepole pine v.t.s. but again can be distinguished by its residual genetic material.

IB2 - ISHBEL 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, IB2, occurs on hummocky landslide deposits (Landslide material) that are variably textured and derived from either calcareous or noncalcareous bedrock. The IB2 Ecosite is dominated by rapidly drained Orthic Regosols, Eluviated Eutric Brunisols, and Eluviated Dystric Brunisols associated with the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) and white spruce/juniper/bearberry (O17) v.t.s.

Geomorphology

The IB2 Ecosite encompasses stabilized landslides (Landslide material) with hummocky surface expression. The landslides often overlie inclined morainal and bedrock slopes on valley walls. These postglacial deposits range from medium acid to extremely calcareous in reaction and, texturally, from silt loam to loamy sand. They have a high content of variably sized angular and subangular coarse fragments and are often fragmental at depth. Very stony and bouldery surfaces are typical. Hummocky surface expression results in a wide range of complex slopes.

Soils

Rapidly drained Orthic Regosols are more common than Orthic Eutric Brunisols and Eluviated Dystric Brunisols as the dominant soils on IB2. These soils develop on landslide material that reflects the nature of the bedrock from which it has been derived. Orthic Eutric Brunisols develop on the more abundant calcareous landslides and Eluviated Dystric Brunisols develop on deposits derived from noncalcareous bedrock. Eluvial (Ae) horizons are more common on noncalcareous material and Orthic Regosols are less abundant. A pedon described in Table 226 and shown in Color Plate 33 illustrates the soil of IB2. This pedon was described on a landslide in the Dormer River valley northwest of Otuskwan Peak in Banff.

Vegetation

The IB2 Ecosite is dominated by the Engelmann spruce-subalpine fir-whitebark pine-lodgepole pine (O4) and white spruce/juniper/bearberry (O17) v.t.s. Open variants of the lodgepole pine/juniper/bearberry (C3) v.t. and unvegetated areas occur as accessories. Minor amounts of lichen-covered colluvial rubble and patches of closed forest are present on IB2. Rubbly, blocky surfaces and lack of soil make tree establishment and growth difficult. A vegetation plot description in Table 227 and shown in Plate 47 illustrates the O17 v.t. on IB2 and represents the vegetation of the sampled pedon described in Table 226. The sampled plot differs from most O17 plots by having no *Arctostaphylos uva-ursi*.

Discussion

The IB2 Ecosite is separated from other Ecosites in the IB Ecosection primarily on vegetational differences as outlined in Table 223. Portions of IB2 most resemble the Miscellaneous Landscape Colluvial Landslide (CL). The latter is differentiated by having nonsoil or Regosols and <20% vegetation cover.

IB3 - ISHBEL 3 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, IB3, occurs on hummocky landslide deposits (Landslide material) that are variably textured and derived from either calcareous or noncalcareous bedrock. The IB3 Ecosite is dominated by well drained Orthic and Eluviated Eutric Brunisols, and Eluviated Dystric Brunisols associated with the Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.s.

Geomorphology

The IB3 Ecosite encompasses stabilized landslides (Landslide material) with hummocky surface expression. The landslide deposits often overlie inclined morainal and bedrock slopes on valley walls and are postglacial deposits that range from medium acid to extremely calcareous in reaction and, texturally, from silt loam to loamy sand. They have a high proportion of variably sized angular and subangular coarse fragments and are often fragmental at depth. Surfaces are very stony and bouldery. Surface expression is hummocky with a wide range of complex slopes. Discontinuous surficial veneers of altered, medium textured eolian material (Eolian material B) occur, especially in western Banff and southwestern Jasper, and often significantly increase the surficial fine earth fraction.

Soils

The IB3 Ecosite is dominated by well drained Orthic and Eluviated Eutric Brunisols and Eluviated Dystric Brunisols. These soils develop on landslide material that reflects the na-

ture of the bedrock from which it has been derived. Orthic and Eluviated Eutric Brunisols develop on the more abundant calcareous landslides. Eluviated Dystric Brunisols develop on landslide deposits derived from noncalcareous bedrock. Well developed soils occur on IB3, possibly due to old surfaces and the accumulation of significant amounts of altered, medium textured eolian material (Eolian material B). A pedon described in Table 228 and shown in Color Plate 34 illustrates the soil of IB3. This pedon has a Bhf horizon that is developed in the eolian veneer. This pedon was sampled on a landslide at the northeast end of Medicine Lake in Jasper.

Vegetation

A variety of Engelmann spruce-subalpine fir v.t.s occur on the IB3 Ecosite. These are best represented by the Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.s. The C21 v.t. more commonly occurs on noncalcareous landslide deposits. Engelmann spruce-subalpine fir/grouseberry (C15) and Engelmann spruce-subalpine fir/heather (O10) v.t.s occur in minor amounts near the Upper Subalpine boundary and in areas affected by cold air drainage. Other v.t.s occurring in minor amounts are the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) and white spruce/buffaloberry/feathermoss (C37) v.t.s. The C37 v.t. occurs on a tract of IB3 in Redearth Creek valley in Banff. A vegetation plot description in Table 229 illustrates the C30 v.t. on IB3. This v.t. is shown in Plate 30 and represents the vegetation of the sampled pedon described in Table 228.

Discussion

The IB3 Ecosite is separated from other Ecosites of the IB Ecosection primarily on vegetational differences as outlined in Table 223. The IB3 Ecosite most resembles the Brazeau 1 (BZ1) Ecosite in terms of similar landform surface expression, soils, and vegetation but is distinguished because BZ1 has residual genetic material. The IB3 Ecosite may also resemble failed till slopes dominated by Engelmann spruce-subalpine fir v.t.s but the till genetic material provides the distinguishing criteria.

JN - JONAS ECOSECTION

The Jonas Ecosection encompasses morainal landforms comprised of noncalcareous, medium textured till (Till B) in the Alpine Ecoregion of Banff and Jasper. Jonas occurs most extensively in the Main Ranges in association with the Miette Group. It also occurs in the Front Ranges in association with noncalcareous Mesozoic (Jurassic and Lower Cretaceous) strata. Valley walls and shoulders, cirque basins, and cols are common physiographic positions in which JN occurs.

A soil pattern involving Dystric and Sombric Brunisols, and Podzols characterizes the soil component of JN. These well to moderately well drained, moderately to well developed soils reflect the acidic, medium textured parent material. Also humus accumulation in upper sola, and the distribution of veneers of altered, medium textured eolian material (Eolian material B) in cool, moist environments contribute to the distinct horizonation. The vegetation component is dominated by heath and mountain avens tundra, the heath tundra being more abundant. Table 230 summarizes the characteristics of the lone Jonas Ecosite (JN1). Fig. 39 shows the position of JN1 in relation to the Egypt (EG) and Sphinx (SX) Ecosites.

JN1 - JONAS 1 ECOSITE

Ecosite Concept

The Alpine Ecosite, JN1, occurs on morainal blankets and veneers consisting of noncalcareous, medium textured till (Till B) overlying inclined, hummocky, and ridged bedrock. A soil pattern relating to the amount of humus accumulation and presence of veneers of altered, medium textured eolian material (Eolian material B) characterizes JN1. Orthic Dystric Brunisols and Orthic Sombric Brunisols are dominant; Eluviated Dystric Brunisols and Orthic Ferro-Humic Podzols are subdominant. Vegetation cover is dominated by the heather-everlasting (L5) and mountain avens-snow willow-moss campion (H1) v.t.s with L5 being more abundant in most areas.

Geomorphology

The JN1 Ecosite is typified by morainal blankets and veneers overlying inclined, hummocky, or ridged bedrock. These moraines consist of noncalcareous, medium textured till (Till B). The low lime phase of Till B occurs in a few areas and is generally associated with Cambrian or younger weakly calcareous strata in central and eastern Banff and Jasper. Veneers of altered, medium textured eolian material (Eolian material B) occur extensively on JN1 tracts of western Banff and southwestern Jasper, sporadically elsewhere. Colluvium derived from till and/or fractured bedrock is found occasionally on steepest portions of the landscape.

Topographically, JN1 is typified by inclined slopes on valley walls and hummocky or ridged surfaces on valley shoulders, cirque basins, and cols. Slopes commonly range from 5 to 45%. Bedrock control of surface expression is characteristic. Failed slopes, including extinct rock glaciers and severely soliflucted slopes, are common (JN1F) and usually have hummocky surfaces that do not necessarily reflect underlying bedrock surfaces. Morainal veneers dominate on JN1X tracts. Bedrock outcrops occur sporadically but are abundant on JN1+R tracts. Patches of colluvium existing as blankets and veneers occur occasionally on the steepest terrain, particularly below bedrock escarpments.

Soils

A soil pattern in which Orthic Dystric and Orthic Sombric Brunisols are dominant and Eluviated Dystric Brunisols and Orthic Ferro-Humic Podzols subdominant characterizes JN1. Under the Alpine conditions, humus accumulation in upper sola is evident, often masking the effects of eluviation. Thus, the well to moderately well drained JN1 soils have varying thicknesses of Ah and/or Ahe horizons. Where veneers of Eolian material B are present, the soils often have Bhf or podzolic Bhf horizons above and Bm or BC horizons below the parent material disconformity.

Soils with Bf or podzolic Bf horizons and Sombric Ferro-Humic Podzols also occur occasionally. Some JN1 soils have, in the lower sola and upper C horizons, clay films thought to be formed by pressure (e.g. freeze - thaw) rather than clay illuviation.

Lithic soil phases are associated with morainal veneers. These dominate on JN1X tracts. Turbic phases of JN1 soils, produced primarily by solifluction, are common, particularly on moderately well, imperfectly, and poorly drained localities with seepage. Physical thickening, rearrangement, mixing, and/or disruption of upper sola horizons are manifestations of the solifluction process. Regosolic soils are found on severely solifluctedand colluviated sites. Imperfectly to poorly drained gleyed Brunisols (especially Gleyed Dystric Brunisols), gleyed Podzols, and Gleysols often occur locally. A few JN1 tracts located on valley floors, usually adjacent to Upper Subalpine Sphinx 1 or 3 (SX1, SX3) tracts, have an uncharacteristically high proportion of imperfectly drained, seepage affected soils.

A pedon illustrating Orthic Dystric Brunisols of JN1 is described in Table 231 and is shown in Color Plate 35. Plate 132 shows the sample site. The till parent material is distinguishable from the underlying noncalcareous, medium textured residuum (Residuum A) in this profile by the abundance, shape, and orientation of coarse fragments. Seepage occurs episodically here and is probably related to the shallowness of unconsolidated materials.

Adjacent pedons better display the effects of solifluction than does this pedon.

Vegetation

The vegetation of JN1 is dominated by the heather-everlasting (L5) and mountain avens-snow willow-moss campion (H1) v.t.s. The L5 v.t. is usually more abundant, particularly in the high snowfall areas along the Continental Divide whereas H1 occurs on some of the more exposed, wind-swept, ridge and hummock crests in western Banff and Jasper. Eastward, H1 becomes increasingly more abundant. On some of the more severely soliflucted, exposed JN1 tracts in eastern Banff and Jasper, H1 is more abundant than L5. A mosaic of vegetated and nonvegetated patches also occur where solifluction and cryoturbation is severe. Accessory v.t.s are white mountain heather-mountain avens-snow willow (L4) and black alpine sedge-everlasting (H2). Both occur in late snow lie localities. The H2 v.t. often occurs in small nivation hollows where snow lies latest and also on meltwater runoff localities. Seepage affected sites have moist to wet v.t.s such as arctic willow-cinquefoil (L7), mountain marigold-globeflower (H9), and fleabane-valerian (H16). Up to 20% krummholz and tree islands are included along lower boundaries of some JN1 tracts. A stand illustrating L5 on JN1 is described in Table 232. This stand is located < 10 km southeast of the pedon sample site.

Discussion

In terms of physiographic position, landform surface expression, and vegetation cover, JN1 resembles the Molar Pass 1 (MP1) and Eiffel 1 (EF1) Ecosites. However, in contrast to JN1 which occurs on Till B, MP1 occurs on morainal landforms consisting of calcareous, medium textured till (Till C); EF1 occurs on noncalcareous, coarse textured till (Till A). Also MP1 has Eutric and Melanic rather than Dystric and Sombric Brunisols. Soils on EF1 are similar to JN1 soils except that stronger profile development results in Eluviated Dystric Brunisols and Orthic Ferro-Humic Podzols being more abundant on EF1. Covarying vegetation distinctions include mountain avens-snow willow-moss campion (H1) being more abundant on MP1 than on JN1, and H1 occurring only occasionally, as an accessory v.t., on EF1. The Egypt 4 (EG4) Ecosite is the Upper Subalpine counterpart of JN1.

KA - KATHERINE ECOSECTION

The Katherine Ecosection is complex and encompasses fluvial aprons and fans throughout the Alpine Ecoregion in Banff and Jasper. These landforms consist of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and calcareous, coarse, stratified fluvial material (Fluvial material B) derived primarily from medium and fine grained clastic strata or associated geomorphic materials. Channeling (Eroded modifier, C.S.S.C. 1978b) and solifluction are common surface features.

Moist to wet conditions (moderately well, imperfectly and poorly drained classes), often with episodic seepage, and disturbance by solifluction and sediment deposition influence soil and vegetation distribution. Regosolic and Gleysolic soils under dwarf shrub-herb meadow and mountain avens tundra vegetation characterize KA. One Ecosite (KA1) is recognized; its features are summarized in Table 233. Katherine occurs most often on lower valley wall slopes and valley floors (Fig. 42). Variable seepage conditions related to snow melt and soil thaw on slopes above KA maintain its moist to wet conditions. It is most extensive in the Front Ranges in association with Mesozoic strata. Occurrences in the Main Ranges are generally related to slaty and shaly strata.

Table 233 General features of the Katherine 1 (KA1) Ecosite.

Ecosite	Landform	Soils	Vegetation

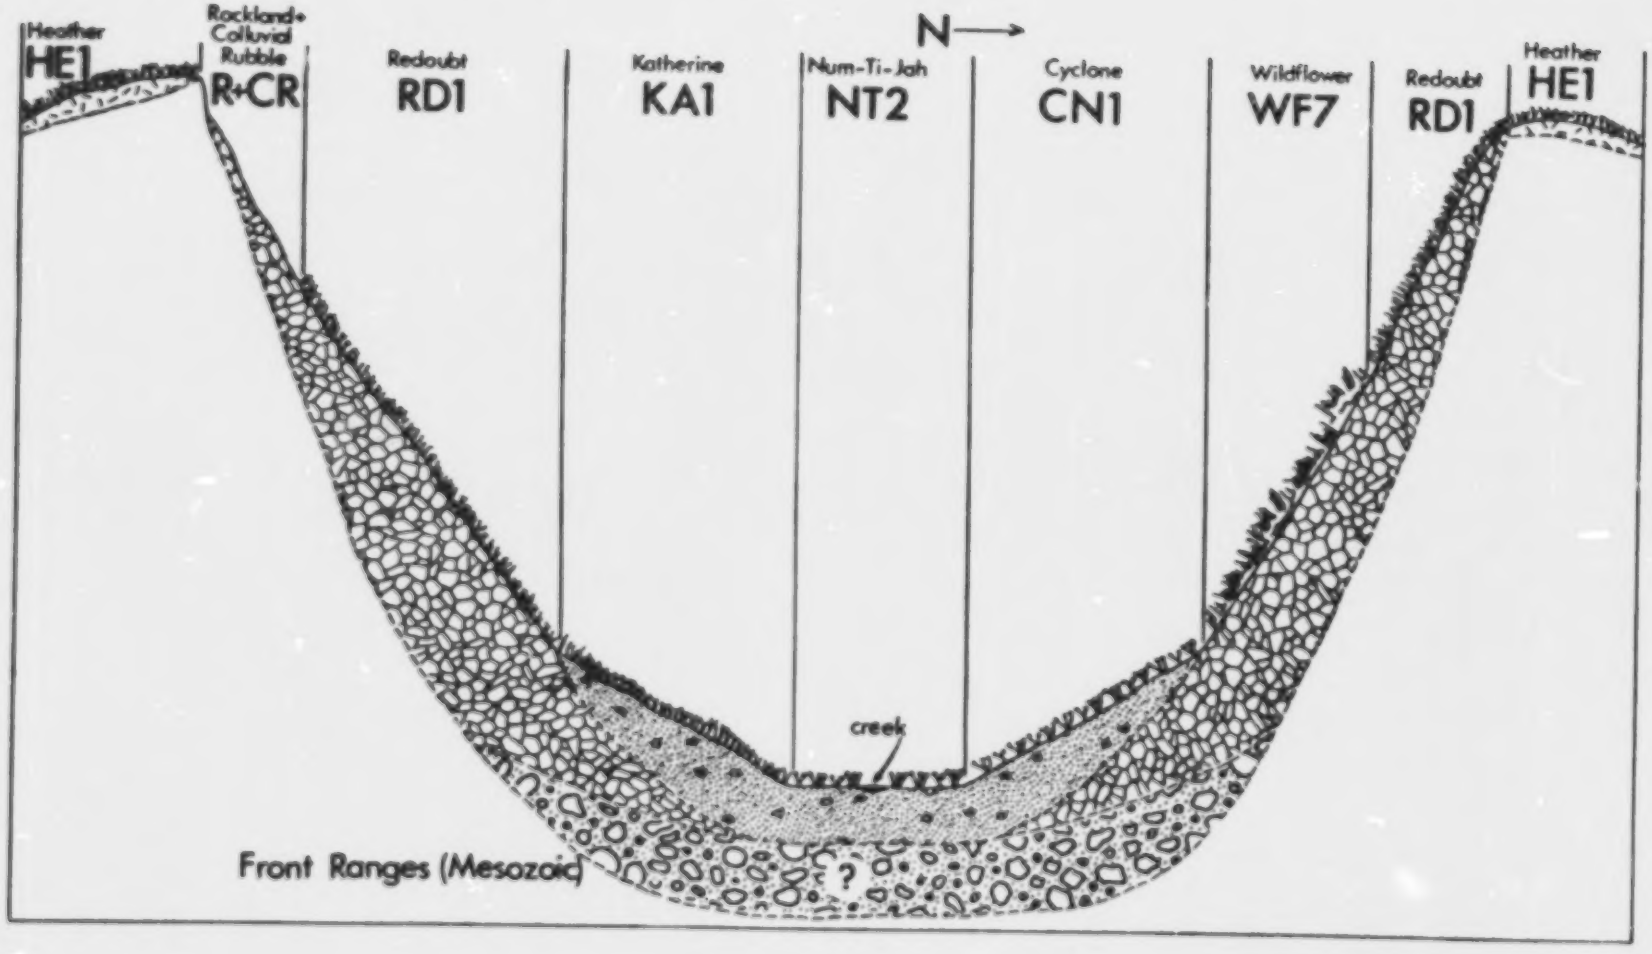
Figure 42 Landscape schematic showing the relationship of the Katherine 1 (KA1) Ecosite to other Ecosites.



KA1 KATHERINE 1 ECOSITE

Ecosite Concept

The Alpine Ecosite, KA1, encompasses moist to wet fluvial aprons and fans comprised of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and calcareous, coarse, stratified fluvial material (Fluvial material B). Surfaces are usually eroded (channeled) and solifluted.

Soils and vegetation of KA1 are related to moisture regime, which reflects seasonal and episodic seepage, and to surface disturbances, mainly solifluction. Cumulic Humic Regosols, Gleyed Cumulic Humic Regosols, and Rego Gleysols dominate KA1 and range from moderately well drained to poorly drained. Vegetation is dominated by the arctic willow-cinquefoil (L7) and mountain avens-snow willow-moss campion (H1) v.t.s.

Geomorphology

The KA1 Ecosite is typified by fluvial aprons and fans consisting of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and calcareous, coarse, stratified fluvial material (Fluvial material B). Veneers and layers of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) occur occasionally. Landforms characterizing KA1 consist of material eroded by fluvial and solifluction processes from morainal, colluvial, and colluvial plus rock slopes. Stratified deposits, including interbedded and mixed humus, are manifestations of episodic fluvial deposition and mixing by solifluction. Solifluction features are more active and extensive on KA1 tracts dominated by material derived from Mesozoic strata than on fluvial material derived from other sources. On several tracts, the fluvial materials are shallow and are underlain by shallow morainal deposits. Small morainal landforms occur sporadically. On gentle, poorly drained slopes, KA1 soils are occasionally thinly mantled by moderately decomposed fen peat derived from sedges and mosses.

Topographically, KA1 displays linear slopes on aprons and fans. Slopes commonly range from 1 to 30% with the gentler slopes being confined to apron and fan toes on valley floors and to minor amounts of level floodplains. Tracts with complex slopes have irregular surfaces reflecting, in part, underlying morainal landforms or rarely occurring bedrock escarpments (KA1+R). Slope continuity is often broken by abandoned and active stream channels including their natural levee margins (Eroded modifier, C.S.S.C. 1978b) and by surface manifestations of solifluction (solifluction lobes, benches and streams; Washburn 1973).

Soils

Soils of the KA1 Ecosite are complex and reflect varying drainage conditions, related to seasonal and episodic seepage, and surface disturbances, mainly solifluction. Cumulic Humic Regosols, Gleyed Cumulic Humic Regosols, and Rego Gleysols best represent KA1 soils and approximate moderately well, imperfectly, and poorly drained conditions, respectively. The Cumulic Humic Regosols and Gleyed Cumulic Humic Regosols receive varying amounts of seasonal and episodic seepage. Under the Alpine conditions, humus accumulations are common on these soils. Consequently, they have varying thicknesses of Ah horizons that, in many cases, have been physically thickened by solifluction processes. Related soils with thin or absent Ah horizons occur as accessories (Cumulic Regosols and Gleyed Cumulic Regosols). Mixing of humus and mineral materials throughout the control section is another manifestation of solifluction. Poorly drained sites that are affected by prolonged seepage and high water tables have more strongly gleyed soils (Rego Gleysols). Organo-mineral Ah horizons are thin or absent on these soils; alternately, thin peat layers have developed in many cases. Mixing of humus and mineral material is not as pronounced in the Rego Gleysols as in the other soils. Some gently sloping KA1 tracts adjacent to lakes and constricted streams are dominated by Rego Gleysols (e.g. near Devon Lakes in Banff). Humic Gleysols, Orthic Regosols, and various Brunisolic soils occur in minor amounts.

A pedon illustrating a Cumulic Humic Regosol of KA1 is described in Table 234 and shown in Color Plate 36. Its high organic carbon content and dark color are normal for genetic materials containing an abundance of carbonaceous Mesozoic shales.

Vegetation

Moisture regime, aspect, and elevation are the predominant influences on KA1 vegetation distribution. The dominant v.t.s are arctic willow-cinquefoil (L7) and mountain avens-snow willow-moss campion (H1). Near the lower elevational limits of KA1, L7 tends to be more abundant on northerly aspects that have imperfect to poor drainage. The H1 v.t. occurs more often on drier sites (moderately well to imperfectly drained) and at higher elevations than L7. Intergrades between the two types are common on KA1. Willow/cinquefoil (S8), white mountain heather-mountain avens-snow willow (L4), water sedge-beaked sedge (H11) and fleabane-valerian (H16) occur as accessory v.t.s. The S8 v.t. occurs on sites similar to those on which L7 occurs. The L4 v.t. is often associated with L7 but on drier sites. The H11 v.t. occurs on gently sloping, often ponded localities adjacent to

Discussion

The KA1 Ecosite encompasses fluvial landscape in the Alpine Ecoregion and is of limited areal extent. It marginally resembles a few other Ecosites. Dry, more steeply sloping portions resemble the Upper Subalpine Cyclone 1 (CN1) Ecosite but can be distinguished by meadow and tundra vegetation in KA1 versus shrub vegetation in CN1. Gently sloping, wet portions of KA1 broadly resemble the Num-Ti-Jah 2 (NT2) Ecosite. However, NT2 in contrast to KA1, includes extensive level floodplain landforms and is dominated by shrubby vegetation. The steepest sloping portions of KA1 occasionally resemble the Alpine colluvial Ecosites, but can be distinguished by their fluvial parent materials.

LV - LARCH VALLEY ECOSECTION

The Larch Valley Ecosection encompasses morainal landforms comprised of noncalcareous, coarse textured till (Till A) in the Upper Subalpine portion of the Subalpine Ecoregion of Banff and Jasper. It occurs in the Main Ranges, primarily on valley walls and shoulders, cirque basins, and cols in areas that are geologically dominated by Cambrian Gog Group quartzites.

The dominant soils, Dystric Brunisols, are comparatively well developed and reflect the acidic, coarse textured parent material in that they are deeply weathered and strongly eluviated. Podzolic soils are subdominant and reflect the presence of altered, medium textured eolian material (Eolian material B). Two groups of coniferous forest and open forest, and a distinctive pattern of tundra plus coniferous open forest differentiate the three Larch Valley Ecosites (Table 236). Fig. 43 shows the Larch Valley (LV) Ecosites in relation to their Lower Subalpine (ML1, ML2) and Alpine (EF1) counterparts.

LV1 - LARCH VALLEY 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, LV1, occurs on morainal blankets consisting of noncalcareous, coarse textured till (Till A) overlying inclined, hummocky, or ridged bedrock. Veneers of altered, medium textured eolian material (Eolian material B) occur extensively and significantly affect soil development. Consequently, LV1 exhibits a pattern of deeply weathered soils in which Eluviated Dystric Brunisols are dominant and Orthic Humo-Ferric Podzols are subdominant. Vegetation cover is dominated by the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. The LV1 Ecosite is least extensive of the Larch Valley Ecosites and is found only in the Main Ranges south of Hector Lake in Banff.

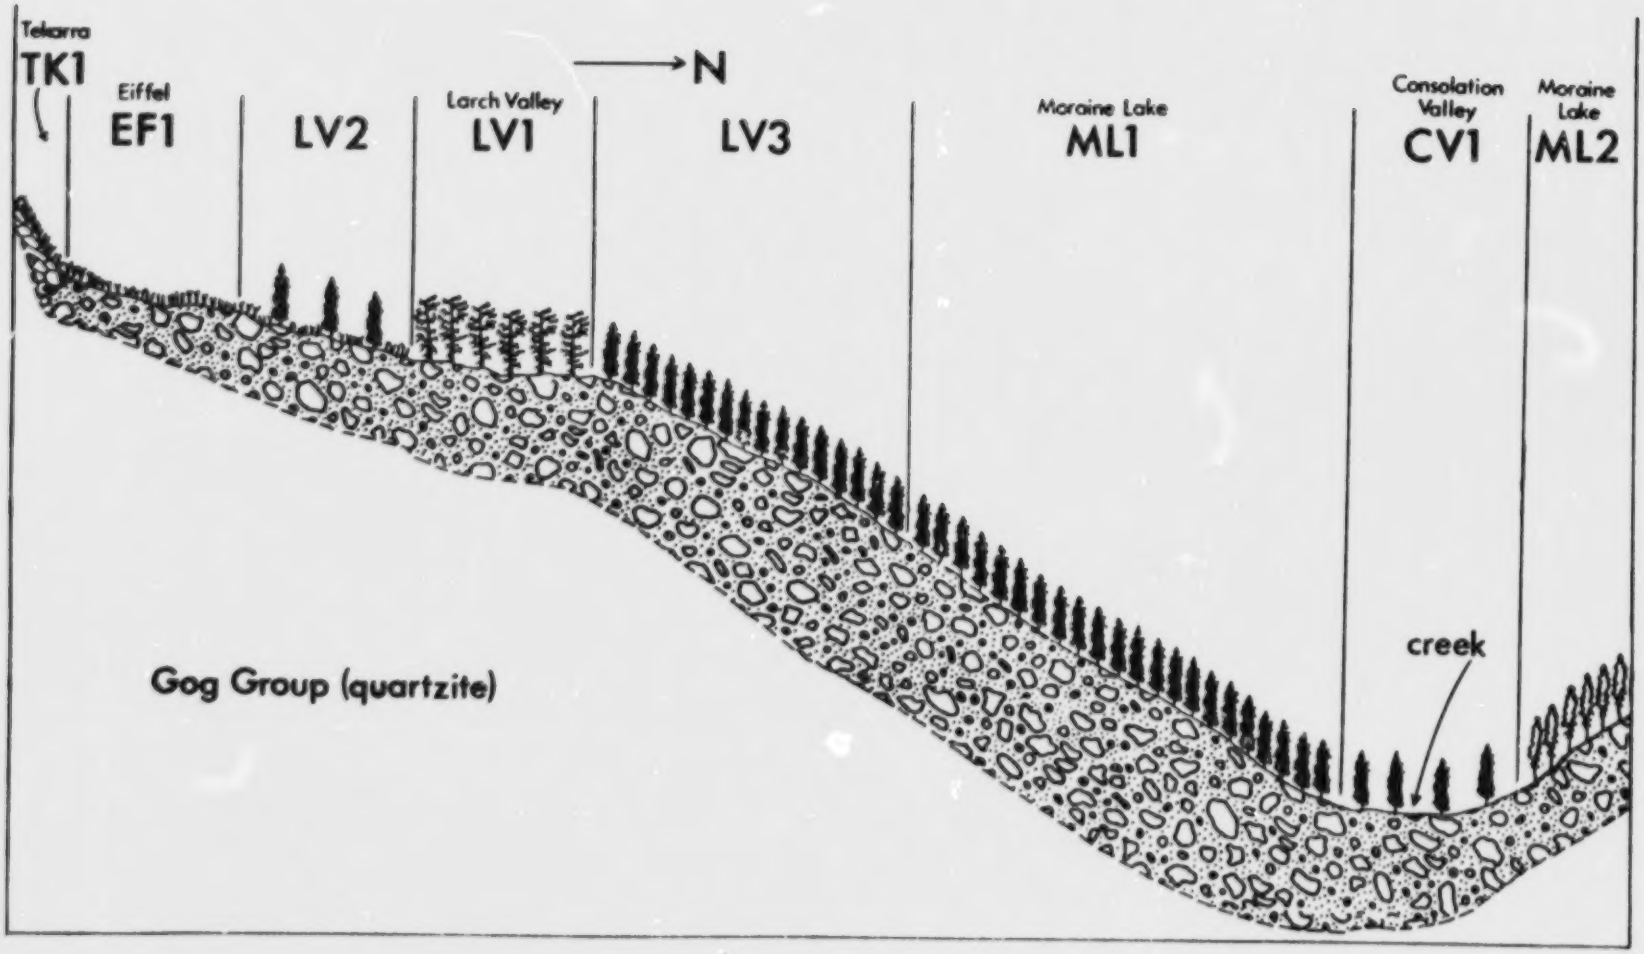
Geomorphology

The LV1 Ecosite is typified by morainal blankets overlying inclined, hummocky, or ridged bedrock. These moraines consist of noncalcareous, coarse textured till (Till A). Veneers of altered, medium textured eolian material (Eolian material B) occur extensively. Colluvium derived from till and fractured bedrock is found occasionally on the steepest portions of the landscape.

Table 236 General features of the Larch Valley (LV) Ecosites.

Ecosite	Landform	Soils	Vegetation
LV1	Till A; blanket	Dystric Brunisol > Podzolic	subalpine larch-subalpine fir forest
LV2	Till A; blanket, veneer	Dystric Brunisol > Sombric Brunisol, Podzolic	heath tundra > Engelmann spruce-subalpine fir open forest
LV3	Till A; blanket	Dystric Brunisol > Podzolic	Engelmann spruce-subalpine fir closed and open forests

Figure 43 Landscape schematic showing the relationship of the Larch Valley (LV) Ecosites to other Ecosites.



Topographically, the LV1 Ecosite displays linear slopes consisting of till mantling inclined bedrock on valley wall slopes (including spur ridges) or hummocky and ridged bedrock of shoulders, cirque basins, and cols. Slopes are normally 15 to 70%. The linear slopes are often gullied. Morainal veneers and bedrock outcrops occur occasionally. In tracts mapped as LV1X, such as the one located at the north end of Panorama Ridge in Banff, the terrain is dominated by morainal veneers and lithic soils. Additionally, bedrock outcrops occur locally along ridge crests and on the steepest portions of the landscape. Patches of colluvium frequently occur below these steep bedrock escarpments. Comparatively deep till deposits, usually with a hummocky surface form, occur occasionally on cirque floors and failed slopes.

Soils

Eluviated Dystric Brunisols are the dominant soils of the LV1 Ecosite and Orthic Humo-Ferric Podzols are the subdominant soils. These well drained soils reflect the presence of nearly continuous veneers of altered, medium textured eolian material (Eolian material B) in that they have Bf or podzolic Bf horizons above and Bm horizons below the parent material disconformity. In addition, their deep sola reflect the acidity and the highly pervious nature of the coarse textured, till genetic materials. Weak cementation (duric tendencies) in lower Bm or BC horizons may also occur. Orthic Dystric Brunisols and others lacking well develop Ae horizons occur in localities recently affected by erosional processes such as avalanching, gullying or shallow surface colluviation or where significant humus input masks the effects of eluviation. Most LV1 soils show, in their upper sola, humic enrichment often associated with the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. Consequently, soils with Bhf and podzolic Bhf horizons occur occasionally. Small amounts of wet soils associated with seeps occur in depressional portions of the landscape. Lithic soil phases are abundant only on LV1X tracts.

A pedon illustrating Eluviated Dystric Brunisols of the LV1 Ecosite is described in Table 237 and shown in Color Plate 37. It has slightly higher than normal organic carbon content in the upper solum. This combined with some surface disturbance has masked the effects of eluviation. The relatively finer texture in the fine earth fraction of the IIC horizon may be attributable to minor incorporation of Miette Group slates and shales that underlie the noncalcareous, coarse textured till at this site.

Vegetation

The LV1 Ecosite is dominated by the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. Open tree canopy variants of the C23 v.t. occur on exposed sites and along the upper elevational boundaries of LV1 tracts. Stunted variants or other avalanche v.t.s such as subalpine fir-willow (S2) occur on avalanche paths. Because of map scale limitations, many LV1 tracts have minor amounts of Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) or Engelmann spruce-subalpine fir/heather (O10) along lower elevational boundaries and patches of heather-everlasting (L5) along upper boundaries. Various moist to wet Upper Subalpine v.t.s plus the C23 v.t. are associated with seeps in depressional sites. A stand representing vegetation of the pedon sampling site described above (Table 237) and illustrating the C23 v.t. of the LV1 Ecosite is depicted in Table 238 and Plate 134.

Discussion

The LV1 Ecosite is the least extensive of the Larch Valley Ecosites. Its distribution is governed by the narrow elevational (2200-2400 m) and geographic range of the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. on noncalcareous, coarse textured till (Till A). In terms of physiographic position, landform surface expression, and vegetation, LV1 resembles the Egypt 2 (EG2) and Peyto Lake 3 (PL3) Ecosites. However, EG2 is distinguished because it occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B), whereas PL3 is distinguished because it occurs on calcareous, medium textured till (Till C). Also, PL3 is dominated by Eutric Brunisols with relatively thin sola. The EG2 Ecosite exhibits similar but thinner soil development compared to LV1 soils. The LV2 and LV3 Ecosites are primarily differentiated by vegetation as outlined in Table 236.

LV2 - LARCH VALLEY 2 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, LV2, occurs on morainal blankets and veneers consisting of noncalcareous, coarse textured till (Till A) overlying inclined, hummocky, and ridged bedrock. The dominant soils are deeply weathered Eluviated Dystric Brunisols. Orthic Dystric Brunisols, Orthic Sombric Brunisols, and Orthic Ferro-Humic Podzols are subdominant and reflect high humus input from the vegetation and, in some localities, the presence of altered, medium textured eolian material (Eolian material B). A distinct pattern comprised of the heather-everlasting (L5) v.t. interspersed with islands of the Engelmann spruce-subalpine fir/heather (O10) v.t. characterizes the vegetation component of this Ecosite.

The LV2 Ecosite represents the uppermost part of the Upper Subalpine on noncalcareous, coarse textured till and is normally bounded above by Alpine Ecosites and below by Upper Subalpine Ecosites with closed to open forests of Engelmann spruce-subalpine fir or subalpine larch-subalpine fir.

Geomorphology

The LV2 Ecosite is typified by morainal blankets and veneers overlying inclined, hummocky, or ridged bedrock. These moraines consist of Till A. Veneers of altered, medium textured eolian material occur extensively on LV2 tracts located in Western Banff and southwestern Jasper and sporadically on tracts of other areas. Colluvium derived from till and/or fractured bedrock is found occasionally on steepest portions of the landscape.

Topographically, the LV2 Ecosite displays linear slopes consisting of till mantling inclined bedrock on upper valley slopes (including spurs) or hummocky and ridged bedrock on valley shoulders, cirque basins, and cols. Slopes of 5 to 70% are common. Morainal veneers dominate on LV2X tracts. Bedrock outcrops are most common on tracts mapped as LV2X and LV2+R. Patches of colluvium existing as blankets and veneers occur occasionally on the steepest terrain. Slopes dissected by gullies occur occasionally. Comparatively deep till deposits, usually with a hummocky surface form, occur occasionally on cirque floors and on failed slopes.

Soils

Eluviated Dystric Brunisols are the dominant soils of the LV2 Ecosite. Orthic Dystric Brunisols, Orthic Sombric Brunisols, and Orthic Ferro-Humic Podzols are subdominant. These well drained soils have deep sola that reflect the acidity and the highly pervious nature of the coarse textured, till genetic material. Weak cementation (duric tendencies) in the lower Bm or BC horizons may also occur. The vegetational characteristics of the heather-everlasting (L5) v.t. appear to result in organic matter additions to the surfaces of these soils that are significantly greater than on other Larch Valley Ecosite soils. Thus, the effects of eluviation are often masked by dark colored organic matter, particularly where altered, medium textured eolian material (Eolian material B) is present, resulting in LV2 soils that have varying thicknesses of Ah and/or Ahe horizons. In addition, where veneers of altered, medium textured eolian material are present, these soils often have Bhf or podzolic Bhf horizons above and Bm horizons below the parent material disconformity. Soils with Bf and podzolic Bf horizons occur occasionally. Lithic soil phases associated with the morainal veneers are relatively common, particularly in tracts of LV2X where they dominate. Localities with turbic soil phases produced by solifluction and cryoturbation occur occasionally but are less abundant than in the Peyto Lake 4 (PL4) and Egypt 2 (EG2) Ecosites found in similar situations but on different genetic materials. Depressional localities with seepage affected, wet soils may constitute up to 15% of LV2 tracts.

A pedon illustrating Eluviated Dystric Brunisols of the LV2 Ecosite is described in Table 239 and shown in Color Plate 38. Solifluction on this site has modified the upper solum as manifested by a relatively high clay content in the Ah horizon and mixing of eolian and till material in the Bm horizon thus diluting its iron and aluminum content.

Vegetation

The LV2 Ecosite is dominated by a vegeta-

tion pattern in which the heather-everlasting (L5) v.t. is more abundant than the Engelmann spruce-subalpine fir/heather (O10) v.t. The O10 v.t. normally exists as discrete patches or islands of trees but includes islands of krummholz on exposed sites or at the Upper Subalpine-Alpine boundary. Within the elevational range of LV2, tree islands cover about 50% of the landscape at lowest elevations, 5% at highest elevations. Islands of the subalpine larch-subalpine fir/grouseberry-everlasting (C23) v.t. often replace O10 on LV2 tracts located in southwestern Banff. Patches of the white mountain heather-mountain avens-snow willow (L4) v.t. and the mountain avens-snow willow-moss campion (H1) v.t. occur occasionally, with H1 being restricted to exposed ridge and hummock crests. Seepage affected depressional localities often have moist to wet Upper Subalpine v.t.s such as fleabane-valerian (H16) or cottongrass/moss (H10). Modification by avalanching and fire, although difficult to identify on LV2 vegetation, occurs occasionally. A stand representing vegetation of the pedon sample site described above (Table 239) and illustrating the O10 v.t. segment of the LV2 vegetation pattern is depicted in Table 240 and Plate 135.

Discussion

The LV2 Ecosite represents the Upper Subalpine-Alpine ecotone on noncalcareous, coarse textured till (Till A). In terms of physiographic position, landform surface expression, and vegetation, LV2 resembles the Egypt 4 (EG4) and Peyto Lake 4 (PL4) Ecosites. However, EG4 can be distinguished because it occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B) and PL4 can be distinguished because it occurs on calcareous, medium textured till (Till C). Also EG4 exhibits taxonomically similar but thinner soil development than LV2 and PL4 is dominated by Eutric and Melanic rather than Dystric and Sombric Brunisols. The LV1 and LV3 Ecosites are primarily differentiated by vegetation as outlined in Table 236.

LV3 - LARCH VALLEY 3 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, LV3, occurs on morainal blankets consisting of noncalcareous, coarse textured till (Till A) overlying inclined bedrock on valley walls. The dominant soils are deeply weathered, strongly leached Eluviated Dystric Brunisols. Orthic Humo-Ferric Podzols are subdominant and are associated with veneers of altered, medium textured eolian material (Eolian material B). Vegetation cover is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), and Engelmann spruce-subalpine fir/heather (O10) v.t.s.

Geomorphology

The LV3 Ecosite is typified by morainal blankets overlying inclined bedrock on valley walls. These moraines consist of noncalcareous, coarse textured till (Till A). The LV3 Ecosite is associated with Cambrian Gog Group quartzites except for a few tracts. A tract mapped as LV3FA near Pipestone Pass warden cabin in Banff contains till derived from the Mount Wilson Formation. Source rocks for the LV3 tracts at Palliser Pass in Banff are inferred to be quartz sandstone layers of the Rocky Mountain Group. Surface veneers of altered, medium textured eolian material (Eolian material B) are extensively distributed over LV3 tracts of western Banff and southwestern Jasper and sporadically distributed in northern Jasper. Colluvium

derived from till and/or fractured bedrock is found occasionally on the steepest portions of the landscape. Noncalcareous, coarse textured ice contact stratified drift (Ice Contact Stratified Drift A) occurs rarely.

Topographically, the LV3 Ecosite displays long linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes are normally 15 to 70% and are often dissected by parallel gullies oriented perpendicular to the contour. Small fluvial fans and aprons emanating from gully mouths along the valley bottom or other major slope breaks may be included in LV3 tracts. Patches of colluvium existing as blankets and veneers occur occasionally on the steepest terrain. Tracts mapped as LV3 situated along valley bottoms, at valley confluences, on valley shoulders, in cirque basins, and on failed slopes often display morainal landforms with irregular surfaces and complex topography (5-45% slopes). These landforms include morainal blankets and veneers overlying ridged and hummocky bedrock and the relatively deep till of hummocky moraines. Morainal veneers dominate in LV3X tracts. Bedrock outcrops are more common on the irregular terrain than on linear slopes and are especially common on LV3+R tracts.

Soils

The dominant soils of LV3 are well drained Eluviated Dystric Brunisols with comparatively thick sola and thick, well developed, eluvial (Ae) horizons that reflect the acidity and rapidly pervious coarse textures of the parent material. Where altered, medium textured eolian material is present, these Eluviated Dystric Brunisols usually have Bf horizons above and Bm horizons below the parent material disconformity and also somewhat thinner Ae horizons. Intimately associated in this geomorphic setting are the subdominant soils, Orthic Humo-Ferric Podzols, that have podzolic Bf horizons above the parent material disconformity. Soils with Bhf and podzolic Bhf horizons also occur occasionally. Weak cementation (duric tendencies) in lower Bm or BC horizons below the parent material disconformity occurs often in LV3 soils. Orthic Dystric Brunisols occur in localities recently affected by erosional processes such as avalanching, gullying, or shallow surface colluviation. Some gullies and depressional localities contain seeps and associated wet soils. Lithic soil phases are not common except on tracts mapped as LV3X where they dominate.

A pedon illustrating Eluviated Dystric Brunisols of the LV3 Ecosite is described in Table 241 and shown in Color Plate 39. Plate 34 shows the sampling site. Texture in the C horizon is coarser than modal for LV3 soils. Coarse fragments are dominantly angular because of the relatively short distance between the till's source area and the sample site.

Vegetation

The LV3 Ecosite is dominated by the Engelmann spruce-subalpine fir/grouseberry (C15), Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21), and Engelmann spruce-subalpine fir/heather (O10) v.t.s. The C15 v.t. is most abundant at low elevations above the boundary between the Lower and Upper Subalpine, and on southerly aspects. The C21 replaces C15 throughout northern Jasper (north of the range of *Vaccinium scoparium*) and on many LV3 tracts near the Continental Divide. The O10 v.t. occurs at higher elevations than C15 or C21 and is most extensive on northerly aspects. The accessory v.t., Engelmann spruce-subalpine fir/heather/feathermoss (C34), often occurs at higher elevations than C15 or C21 and below O10. Various moist to wet Upper Subalpine v.t.s are associated with seeps found in some gullies and depressional sites. Avalanche v.t.s such as subalpine fir-willow (S2) occur on avalanched tracts (LV3A). Fire affected vegetation in which spruce is regenerating occurs in some areas.

A stand illustrating the C15 v.t. of the LV3 Ecosite is described in Table 242. This stand is located a short distance up valley from the pedon sample site described above (Table 241). It has a low cover of *Vaccinium scoparium* compared to the central concept of the C15 v.t.

Discussion

The LV3 Ecosite is the most extensive of the Larch Valley Ecosites. In terms of physiographic position, landform surface expression, and vegetation, LV3 resembles the Egypt 1 (EG1) and Peyto Lake 1 (PL1) Ecosites. However, EG1 occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B) and PL1 occurs on calcareous, medium textured till (Till C) which distinguishes it from LV3. Also EG1 exhibits taxonomically similar but thinner soil development compared to LV3 and PL1 is dominated by Eutric rather than the Dystric Brunisols of LV3. The LV1 and LV2 Ecosites are primarily differentiated from LV3 by vegetation as outlined in Table 236.

MC - MERLIN CASTLE ECOSECTION

The Merlin Castle (MC) Ecosection is characterized by veneers and blankets of calcareous, fine textured glaciolacustrine material overlying ridged, hummocky, and undulating slopes of calcareous glacial materials. Its complex topography forms a wet and dry landscape pattern. Wet depressional areas comprise about 80% of the landscape and are dominated by Gleysolic and gleyed Brunisolic soils and wet spruce open forest and birch fen. The dry portions of the landscape are

dominated by Luvisolic and Brunisolic soils and lodgepole pine and Engelmann spruce—subalpine fir forests.

The MC Ecosection occurs in the Lower Subalpine portion of the Subalpine Ecoregion in both both Banff and Jasper. It occupies valley floor benchland positions in the lower Rocky and upper Miette River valleys in Jasper and the Pipestone and Mistaya River and Johnston Creek valleys in Banff.

The MC Ecosection is represented by only one Ecosite (MC1). The general features of this Ecosite are outlined in Table 243. Fig. 44 shows the position of MC1 on the landscape.

MC1 - MERLIN CASTLE 1 ECOSITE

Ecosite Concept

The Merlin Castle 1 (MC1) Ecosite represents a wet and dry landscape pattern characterized by veneers and blankets of calcareous, fine textured glaciolacustrine material overlying ridged, hummocky, and undulating slopes of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). The wetland portion of MC1 dominates about 80% of the landscape and is typified by poorly drained Orthic and Rego Gleysols and Gleyed Eutric Brunisols associated with the spruce/Labrador tea/brown moss (O11) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s. The dry portion of MC1 is typified by Orthic and Brunisolic Gray Luvisols and Eluviated Eutric Brunisols associated with the lodgepole pine/Labrador tea (C29) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) v.t.s.

Geomorphology

The MC1 Ecosite displays a compound wet and dry landscape characterized by veneers and blankets of calcareous, fine textured glaciolacustrine material overlying ridged, hummocky, and undulating slopes of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). Minor amounts of calcareous, fine textured glaciolacustrine material overlying noncalcareous, coarse textured ice contact stratified drift (Ice

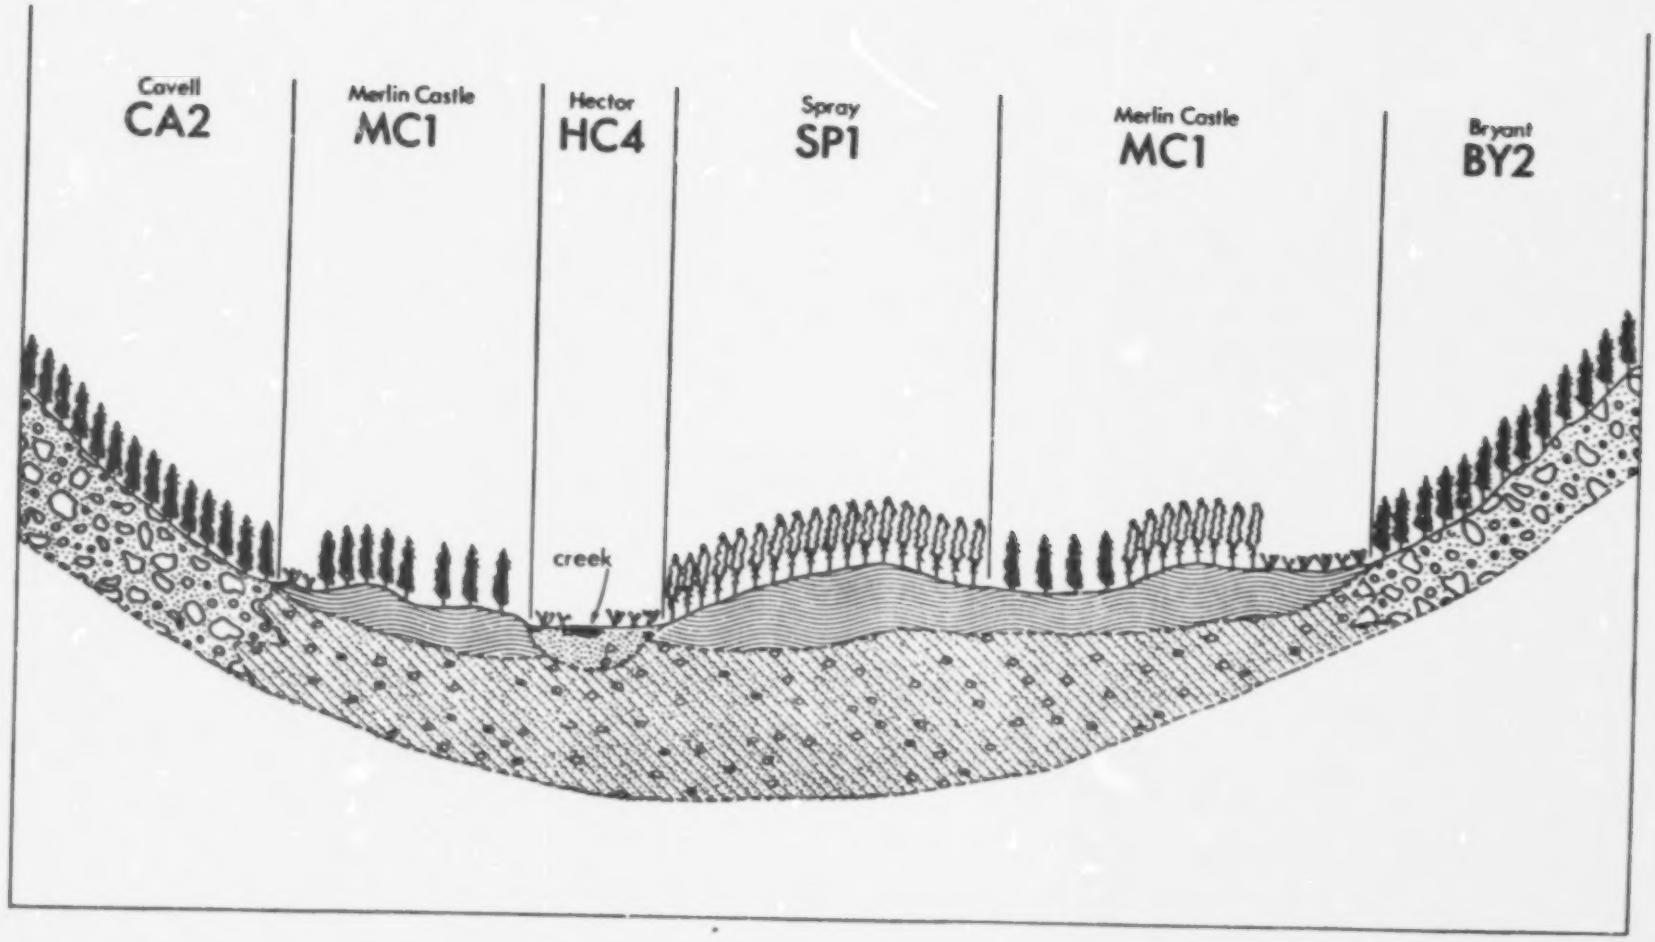
Figure 44 Landscape schematic showing the relationship of the Merlin Castle 1 (MC1) Ecosite to other Ecosites.



Contact Stratified Drift A) occur in the upper Miette River valley in Jasper. In some tracts calcareous, medium textured till (Till C) is the underlying genetic material. Terraces consisting of calcareous, fine textured glaciolacustrine material overlying calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) occur locally on some tracts. The dominantly wet depressional areas on MC1 usually have thin organic veneers of fen peat and veneers of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A). Seepage and other surface waters accumulate on the landscape. Slow perviousness of the glaciolacustrine material and slow runoff on the gentle slopes result in poorly drained soils and high, possibly perched, water tables. Surficial veneers of altered, medium textured eolian material (Eolian material B) occur on the dry segments. Topographically, the MC1 Ecosite is dominated by wet depressions with occasional raised ridges breaking up the continuity of the wetland. Slopes are complex, commonly ranging from 0 to 10%. Tracts of MC1 with steeper, often linear inclined slopes occur occasionally.

Soils

Soils of the MC1 Ecosite are distributed in a pattern governed by drainage conditions. A set of pedogenically related soils occurs on the poorly drained segment. They are best represented by Orthic and Rego Gleysols, and Gleyed Eutric Brunisols. Strength of gleying, reflecting degree of saturation, is variable. Long periods of saturation inhibit pedogenic horizonation (Rego Gleysols). Orthic Gleysols and Gleyed Eutric Brunisols reflect shorter periods of saturation. The presence of eolian and fluviolacustrine veneers containing primary minerals promotes the development of iron, aluminum, and humus-enriched B and podzolic B horizons. Gleyed Podzolic soils occur in minor amounts. Many of these soils have thin organic veneers, usually of moderately decomposed fen peat. The accessory soils, Terric Mesisols, occur where the fen peat is >40 cm thick, usually under very poorly drained conditions (ponding). Other Organic soils with subdominant humic and fibric layers, gleyed Regosolic soils and Humic Gleysols occur occasionally. A pedon illustrating a Gleyed Eutric Brunisol of the wet portion of MC1 is described in Table 244 and shown in Color Plate 40. Plate 136 shows the sample site. By their textural characteristics, the Ahgj and Bfjgj horizons are developed in altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A). Because of its high clay content the Bfjgj horizon meets all but the iron plus aluminum to clay ratio specified for Bf horizons (C.S.S.C. 1978b), a feature common to MC1 soils with these veneers. This pedon was sampled in the Mistaya River valley between Chephren and Waterfowl Lakes in Banff.

The dry portion of MC1 is dominated by well to moderately well drained Orthic and Brunisolic Gray Luvisols, and Eluviated Eutric Brunisols. These soils have a clay increase giving textural B horizons, many with clay films evident in hand specimens (Bt horizons), occurring at or near the glaciolacustrine surface. Iron, aluminum, and humus enriched Bm horizons develop in veneers of altered, medium textured eolian material (Eolian material B), where present, and overlie the textural B horizons. The pedon description in Table 337 for the Spray 1 (SP1) Ecosite illustrates Orthic Gray Luvisols on the dry portions of the MC1 Ecosite.

Vegetation

Vegetation on MC1 is distributed in a pattern governed by drainage conditions. The wet portion of MC1 is dominated by the spruce/Labrador tea/brown moss (O11) and dwarf birch-shrubby cinquefoil/needlerush (S3) v.t.s on poorly drained sites. The accessory v.t., dwarf birch-shrubby cinquefoil-willow/brown moss (S1), occurs on similarly drained sites. The water sedge-beaked sedge (H11) and black spruce-lodgepole pine/willow/sedge (C8) v.t.s occur in minor amounts. A stand illustrating the O11 v.t. on the wet landscape of MC1 is described in Table 245.

A variety of lodgepole pine and Engelmann spruce-subalpine fir v.t.s, best represented by lodgepole pine/Labrador tea (C29) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30), occur on the dry portion of MC1. The lodgepole pine/buffaloberry/grouseberry (C18) is an accessory v.t. occurring on tracts of MC1 in the Pipestone and Mistaya River valleys in Banff. Small amounts of the Engelmann spruce-subalpine fir/heather (O10) v.t. occur on a tract of MC1 in the upper Miette River valley in Jasper. The Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t. occurs in minor amounts on tracts in the Pipestone River valley in Banff. Lodgepole pine is common on tracts mapped as MC1B in the Pipestone River valley. A vegetation plot description of a C29 v.t. in Table 338 for the Spray 1 (SP1) Ecosite also illustrates the C29 v.t. on the dry landscape of MC1.

Discussion

The characteristics of the dry landscape of MC1 are identical to those of the Spray 1 (SP1) Ecosite and the two often occur adjacent on the landscape. Where SP1 tracts occur as dry islands in a wet landscape and are too small to delineate they are considered part of the MC1 concept. The MC1 Ecosite most resembles Consolation Valley 1 (CV1) displaying a similar drainage induced pattern. However, CV1 occurs on morainal landforms rather than calcareous, fine textured glaciola-

custrine material. The Nashan 1 (NH1) Ecosite is the Montane counterpart of MC1. The majority of MC1 is mapped in the Mistaya and Pipestone River valleys in Banff.

ML - MORAINE LAKE ECOSECTION

The Moraine Lake Ecosection encompasses morainal landforms comprised of noncalcareous, coarse textured till (Till A) throughout the Lower Subalpine portion of the Subalpine Ecoregion in the Main Ranges of Banff and Jasper. It occurs primarily on valley walls in portions of main and tributary valleys that are geologically dominated by Cambrian Gog Group quartzites.

The dominant soils, Dystric Brunisols, reflect the acidic, coarse textured parent material in that they are deeply weathered and strongly eluviated. Three groups of coniferous forest vegetation differentiate the three Moraine Lake Ecosites (Table 246). Fig. 43 shows the ML1 and ML2 Ecosites in relation to their Upper Subalpine (LV1, LV2, LV3) and Alpine (EF1) counterparts.

ML1 - MORAINE LAKE 1 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, ML1, occurs on morainal blankets consisting of noncalcareous, coarse textured till (Till A) overlying inclined bedrock on valley walls. The dominant soils are (relative to others in the study area) deeply weathered, strongly eluviated Eluviated Dystric Brunisols. Orthic Humo-Ferric Podzols are subdominant and are associated with veneers of altered, medium textured eolian material (Eolian material B). Vegetation cover is dominated by the Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s.

Geomorphology

The ML1 Ecosite is typified by morainal blankets overlying inclined bedrock on valley walls. These moraines consist of noncalcareous, coarse textured till (Till A) but include a low lime phase. Surface veneers of altered, medium textured eolian material (Eolian material B) are extensive over ML1 tracts of

Table 246 General features of the Moraine Lake (ML) Ecosites.

Ecosite	Landform	Soils	Vegetation
ML1	Till A; blanket	Dystric Brunisol > Podzolic	Engelmann spruce-subalpine fir forest
ML2	Till A; blanket	Dystric Brunisol	lodgepole pine forest
ML3	Till A; blanket	Dystric Brunisol	Engelmann spruce-whitebark pine forest

western Banff and southwestern Jasper, and are sporadic in northwestern Jasper. Colluvium derived from till and/or fractured bedrock is found occasionally on the steepest portions of the landscape. Ice contact stratified material occurs rarely.

Topographically, the ML1 Ecosite displays long linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes are normally 15 to 70%. Morainal veneers occur occasionally; bedrock outcrops rarely. Small localities dominated by colluvial blankets and veneers occur occasionally on the steepest terrain. The linear till slopes are often dissected by parallel gullies oriented perpendicular to the contour. Small fluvial fans and aprons may occur at gully mouths at a major break in slope (usually the valley bottom) and are included in ML1 tracts if too small to be delineated as fluvial Ecosites. Tracts mapped as ML1 situated along broad valley bottoms, at valley confluences, on failed slopes, and occasionally in valley headwall areas often have irregular surfaces with complex slopes (usually 5-45%). These landforms include morainal blankets overlying ridged or hummocky bedrock and the relatively deep till of hummocky moraines.

Soils

The dominant soils of ML1, well drained Eluviated Dystric Brunisols, have comparatively thick sola and thick, well developed, eluvial (Ae) horizons that reflect the acidity, rapid permeability, and coarse textures of the parent material. Where altered, medium textured eolian material is present, these Eluviated Dystric Brunisols usually have Bf horizons above and Bm horizons below the parent material disconformity and somewhat thinner Ae horizons. Intimately associated in this geomorphic setting are the subdominant Orthic Humo-Ferric Podzols that have podzolic Bf horizons above the parent material disconformity. Soils with Bhf and podzolic Bhf horizons also occur occasionally. Weak cementation in lower Bm or BC horizons below the parent material disconformity occurs often in ML1 soils. Orthic Dystric Brunisols occur in localities recently affected by erosional processes such as avalanching, gullying, or shallow surface colluviation. Some gullies contain seeps with which various wet soils are associated. Lithic soil phases occur occasionally.

A pedon illustrating Eluviated Dystric Brunisols of the ML1 Ecosite is described in Table 247. It differs from modal ML1 soils by its relatively high organic carbon content in the upper solum, high pH and lime content in the parent material. The carbonate is attributable to the localized presence of calcareous erratics in the noncalcareous, coarse textured till of the sampling area.

Vegetation

The ML1 Ecosite is dominated by the Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) v.t.s. Overall, C14 is most abundant but some ML1 tracts are dominated by C13 or C21. The C13 v.t. is more common along the eastern side of the Main Ranges and on gently sloping lower slopes below C14 or C21 dominated valley walls. The C21 v.t. is more abundant in northern Jasper along the Continental Divide, particularly where low passes dissect the Divide. Minor amounts of Engelmann spruce-whitebark pine/false azalea (C12) and Engelmann spruce-subalpine fir/Labrador tea/crowberry (C30) occur occasionally in west central and northern Jasper. Wet v.t.s such as Engelmann spruce-subalpine fir/rock willow/bracted lousewort (O14) are associated with seeps. Snow avalanche v.t.s such as subalpine fir-willow (S2) occur on avalanched portions. Fire affected vegetation in which spruce rather than pine is regenerating occurs in some areas (e.g. west of Sunwapta River opposite Beauty Creek in Jasper).

A stand that illustrates the C14 v.t. of the ML1 Ecosite is described in Table 248. This stand is located at about the same elevation on the same slope as the pedon sampling site but <1 km up valley. The occurrence of *Senecio triangularis* and *Erigeron peregrinus* suggests that the site is moister than modal for ML1.

Discussion

The ML1 Ecosite is the most extensive of the Moraine Lake Ecosites. In physiographic position, landform surface expression, and vegetation, ML1 resembles the Cavell 2 (CA2) and Bryant 1 and 2 (BY1, BY2) Ecosites. However, rather than the Till A associated with ML1, CA2 occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B) and BY1 and BY2 occur on calcareous, medium textured till (Till C). Also BY1 and BY2 are dominated by Eutric Brunisols with thin sola rather than Dystric Brunisols. In addition to Eluviated Dystric Brunisols, CA2 has significant amounts of Orthic Dystric Brunisols. Soils of CA2 are not as deeply weathered and strongly eluviated as ML1 soils. The ML2 and ML3 Ecosites are differentiated from ML1 by their vegetation as outlined in Table 246.

ML2 - MORAINE LAKE 2 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, ML2, occurs on morainal blankets consisting of noncalcareous, coarse textured till (Till A) overlying

inclined bedrock on valley walls. The dominant soils are deeply weathered, strongly eluviated Eluviated Dystric Brunisols. Vegetation cover is dominated by the lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/false azalea/grouseberry (C20) v.t.s. The ML2 Ecosite is more extensive in Jasper than in Banff.

Geomorphology

The ML2 Ecosite is typified by morainal blankets overlying inclined bedrock on valley walls. These moraines consist of Till A. Colluvium derived from till and/or fractured bedrock is found occasionally of the steepest portions of the landscape. Ice contact stratified material occurs rarely, although the landform pattern and textural characteristics of material observed along the upper Brazeau River below Four Point Creek in Jasper may be the result of ice margin stream erosion. Although ML2 is usually associated with Cambrian Gog Group quartzites, an ML2A tract located north of Cascade Mountain in Banff is associated with quartz sandstone of the Rocky Mountain Group. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically. Most ML2 tracts, excepting those at the southern end of the Wapituk Range in Banff, are located outside the area of extensive Eolian material B veneers and erosion subsequent to fires has removed much of the deposit.

Topographically, the ML2 Ecosite displays long linear slopes consisting of till mantling the inclined bedrock that forms valley walls. Slopes are normally 15 to 70%. Morainal veneers occur occasionally and bedrock outcrops rarely except in tracts mapped as ML2X such as those located in the Athabasca River valley below Lick Creek in Jasper. These tracts have morainal veneers, lithic soils, and some bedrock escarpments. Small localities dominated by colluvial blankets and veneers occur occasionally on the steepest terrain. The linear till slopes are often dissected by parallel or subparallel gullies oriented perpendicular to the contour. Small fluvial fans and aprons may occur at gully mouths at a major break in slope (usually the valley bottom) and are included in ML2 tracts if they are too small to delineate as fluvial Ecosites. Tracts mapped as ML2 situated along broad valley bottoms, at valley confluences, and on failed slopes often have irregular surfaces with complex slopes (5-45%). These landforms include morainal blankets overlying ridged or hummocky bedrock and the relatively deep till of hummocky moraines.

Soils

The dominant soils of ML2, well drained Eluviated Dystric Brunisols, have thick sola and thick, well developed, eluvial (Ae) horizons that reflect the acidity, rapid permeability, and coarse textures of the parent material. Weak cementation in lower Bm or BC horizons is a common feature. Orthic Dystric Brunisols occur in localities recently affected by erosional processes such as avalanching, gullying, or shallow surface colluviation. Some gullies contain seeps with which wet soils are associated. Where altered, medium textured eolian material is present, Eluviated Dystric Brunisols and Orthic Humo-Ferric Podzols occur. These soils have

thinner Ae horizons and Bf or podzolic Bf horizons above and Bm horizons below the parent material disconformity. The ML2 tracts situated at the southern end of the Waputik Range in Banff have significant amounts of these soils. Lithic soil phases are not common except on ML2X tracts, such as those located in the Athabasca River valley below Lick Creek in Jasper, where they dominate.

A pedon illustrating Eluviated Dystric Brunisols of the ML2 Ecosite is described in Table 249. Color Plate 41 shows the upper solum of this pedon. It differs from modal ML2 soils by its fine texture in the C horizon. This phenomenon occurs occasionally in this noncalcareous, coarse textured till.

Vegetation

The ML2 Ecosite is dominated by the lodgepole pine/buffaloberry/grouseberry (C18) and lodgepole pine/false azalea/grouseberry (C20) v.t.s that reflect the predominant southerly aspects and fire history. Accessory v.t.s include lodgepole pine/green alder/feathermoss (C10), lodgepole pine/feathermoss (C11), and lodgepole pine/buffaloberry/twinflower (C19). Occasionally lodgepole pine/buffaloberry/showy aster (C6) occurs on drier localities. Avalanched and severely fire affected vegetation occurs in some localities.

A stand that illustrates the C20 v.t. of the ML2 Ecosite is described in Table 250. This stand is located above Honeymoon Lake in Jasper < 15 km southeast of the ML2 pedon sample site.

Discussion

In physiographic position, landform surface expression and vegetation, ML2 resembles the Cavell 4 (CA4) and Panorama Ridge 1 and 2 (PR1, PR2) Ecosites. However, rather than the Till A of ML2, CA4 occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B), and PR1 and PR2 occur on calcareous, medium textured till (Till C). Also, PR1 and PR2 are dominated by Eutric Brunisols with thin sola and luvisolic tendencies rather than Dystric Brunisols. In addition to Eluviated Dystric Brunisols, CA4 has significant amounts of Orthic Dystric Brunisols. The ML1 and ML3 Ecosites are differentiated from ML2 by vegetation as outlined in Table 246.

ML3 - MORAINE LAKE 3 ECOSITE

Ecosite Concept

The Lower Subalpine Ecosite, ML3, occurs on morainal blankets consisting of noncalcareous, coarse textured till (Till A) overlying inclined bedrock. The dominant soils are deeply weathered, strongly leached Eluviated Dystric Brunisols. Vegetation cover is dominated by the Engelmann spruce-whitebark pine/false azalea (C12) v.t. The ML3 Ecosite is found only in Jasper in the area bounded by Highway 16 to the north, Highway 93 to the east, and the Athabasca and Chaba Rivers to the south. It is restricted to altitudes just below the Upper Subalpine - Lower Subalpine boundary.

Geomorphology

The ML3 Ecosite is typified by morainal blankets overlying inclined bedrock. Colluvium and ice contact stratified drift occur rarely. Surface veneers of altered, medium textured eolian material (Eolian material B) occur sporadically. Most ML3 tracts are located outside the area of extensive Eolian material B veneers and erosion has removed much of the deposit.

Topographically, the ML3 Ecosite displays long linear slopes consisting of till mantling the inclined bedrock of northerly or northeasterly oriented spurs that separate large valleys. The ML3 tract at Geraldine Lookout is a good example. Thinner till deposits resulting

in morainal veneers frequently occur along spur ridge crests. A large tract in the Astoria River valley forms part of the valley wall. Occasionally, complex topography occurs where the bedrock surface is hummocky or on failed slopes, such as the ML3F tract below Verdant Pass in the Whirlpool River valley. Slopes normally range from 30 to 70%. The linear till slopes are often dissected by parallel or subparallel gullies oriented perpendicular to the contour.

Soils

The dominant soils of ML3 are well drained Eluviated Dystric Brunisols with thick sola and thick, well developed, eluvial (Ae) horizons that reflect the acidity, rapid permeability, and coarse textures of the parent material. Weak cementation in lower Bm or BC horizons is a common feature. Orthic Dystric Brunisols occur in localities recently affected by erosional processes such as gullying or shallow surface colluviation. Where altered, medium textured eolian material is present, Eluviated Dystric Brunisols and Orthic Humo-Ferric Podzols occur. These soils have thinner Ae horizons and Bf or podzolic Bf horizons above and Bm horizons below the parent material disconformity. Lithic phases are not common except locally along ridge crests. The pedon described in Table 249 for the ML2 Ecosite also illustrates soils of ML3.

Vegetation

The ML3 Ecosite is dominated by the Engelmann spruce-whitebark pine/false azalea (C12) v.t. Factors involved in this dominance of C12 are not apparent, because ML1 tracts dominated by Engelmann spruce-subalpine fir/false azalea (C14) or Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21) also occur on similar landscape positions throughout the area containing ML3 tracts. Occurences of ML3 have a narrow elevational range, and all ML3 tracts are bounded above by Upper Subalpine Ecosite tracts. A stand illustrating the C12 v.t. of the ML3 Ecosite is described in Table 251.

Discussion

The ML3 Ecosite is the least extensive of the Moraine Lake Ecosites and is of very limited extent relative to the study area. In terms of geographic distribution, physiographic position, landform, genetic material, and soils, ML3 most closely resembles the ML1 Ecosite. Vegetation separates the two: ML3 being dominated by Engelmann spruce-whitebark pine/false azalea (C12), whereas ML1 is dominated by Engelmann spruce-subalpine fir/false azalea (C14), Engelmann spruce-subalpine fir/feathermoss (C13), and Engelmann spruce-subalpine fir/tall bilberry/liverwort (C21). The C12 v.t. also occurs locally on other Ecosites, particularly on rocky or stony (bouldery) sites within various Upper Subalpine Ecosite tracts. The ML3 Ecosite does not, however, have unusually rocky or stony soils.

MP - MOLAR PASS ECOSECTION

The Molar Pass Ecosection encompasses morainal landforms comprised of calcareous, medium textured till (Till C) in the Alpine Ecoregion throughout Banff and Jasper. The MP Ecosection occurs on valley walls and shoulders, cirque basins, and cols, and is associated with calcareous strata. Eutric and Melanic Brunisols, Regosols, and Humic Regosols characterize the soil component of

Table 252 General features of the Molar Pass 1 (MP1) Ecosite.

Ecosite	Landform	Soils	Vegetation
MP1	Till C; blanket, veneer	Eutric and Melanic Brunisol, Regosol, Humic Regosol	mountain avens tundra, heath tundra

MP1. Brunisolic soils are most abundant. Soil distribution reflects the degree of surface stability and weathering of calcareous material and the presence of veneers of altered, medium textured eolian material (Eolian material B). The vegetation component is dominated by mountain avens and heath tundra, the mountain avens tundra being more abundant. Table 252 summarizes the characteristics of the one Molar Pass Ecosite (MP1). Fig. 48 shows, schematically, the position of MP1 in relation to the Peyto Lake (PL) and Sphinx (SX) Ecosites.

MP1 - MOLAR PASS 1 ECOSITE

Ecosite Concept

The Alpine Ecosite, MP1, occurs on morainal blankets and veneers consisting of calcareous, medium textured till (Till C) overlying inclined, hummocky, and ridged bedrock. Soil distribution depends on the degree of surface stability and weathering of calcareous material, and the distribution of veneers of altered, medium textured eolian material (Eolian material B). The dominant soils are Orthic Eutric Brunisols, Orthic Melanic Brunisols, Orthic Regosols, and Orthic Humic Regosols with the Brunisolic soils being most abundant. Vegetation cover is dominated by the mountain avens-snow willow-moss campion (H1) and heather-everlasting (L5) v.t.s with H1 being more abundant in most areas.

Geomorphology

The MP1 Ecosite is typified by morainal blankets and veneers overlying inclined, hummocky, or ridged bedrock. These moraines consist of calcareous, medium textured till (Till C). Veneers of altered, medium textured eolian material (Eolian material B) are most extensive on MP1 tracts of western Banff and southwestern Jasper except on exposed, wind-swept tracts (e.g. Allenby Pass in Banff). In other areas Eolian material B veneers occur sporadically and are very shallow. Colluvium derived from till and fractured bedrock is found occasionally on steepest portions of the landscape.

Topographically, MP1 is typified by inclined slopes on valley walls and hummocky or ridged surfaces on valley shoulders, cirque basins, and cols. Bedrock control of surface expression is characteristic. Failed slopes, including old rock glaciers and severely soliflucted slopes, are common (mapped as MP1F) and usually have hummocky surfaces that do not necessarily reflect underlying bedrock. Slopes commonly range from 5 to 45% but a few tracts with steeper slopes occur. Some of the more steeply sloping tracts are dissected by gullies. Morainal veneers dominate on those tracts mapped as MP1X. Bedrock outcrops occur sporadically but are abundant on MP1+R tracts. Colluvial blankets and veneers occur locally on the steepest terrain, particularly below bedrock escarpments.

Soils

Well to moderately well drained Orthic Eutric Brunisols, Orthic Melanic Brunisols, Orthic Regosols, and Orthic Humic Regosols dominate the MP1 Ecosite. The Brunisolic soils are most abundant and occur on geomorphically stable localities. The Regosolic soils occur on exposed, wind-swept localities lacking veneers of altered, medium textured eolian material (Eolian material B), on severely soliflucted or cryoturbated localities and on very shallow parent material. Regosolic soils dominate on some MP1 tracts that are extensively and severely cryoturbated (e.g. southwest of Mount McConnell in Banff; Plate 137 and Color Plate 42) or that have extensive, extremely shallow parent material in combination with exposed physiographic positions (e.g. Allenby Pass). The Regosolic soils usually occur under mountain avens-snow willow-moss campion (H1) vegetation, rarely with heather-everlasting (L5). Accessory and included v.t.s occasionally have Regosolic soils.

Both Brunisolic and Regosolic soil groups display, under Alpine conditions, humus accumulation in upper sola. Thus, MP1 soils have varying thicknesses of Ah and/or Ahe horizons. In the Brunisolic soils, this accumulation and translocation of humic material usually masks the effects of eluviation, although Eluviated Eutric Brunisols occur as accessory soils on locally stable sites. Normally Bm horizons display humus accumulation but are otherwise weakly to moderately developed. Where veneers of altered, medium textured eolian material (Eolian material B) are present, the soils often have strongly developed Bm, Bhf or podzolic Bhf horizons above, and weakly developed Bm or BC horizons below the parent material disconformity. Orthic Ferro-Humic Podzols are accessory soils and are most abundant in western Banff and southwestern Jasper. Soils with Bf and

podzolic Bf horizons and Sombric Ferro-Humic Podzols also occur occasionally. Some Bm horizons developed in the till may show the rudimentary luvisolic tendencies (clay increases) associated with weathering of calcareous materials.

Lithic soil phases are associated with morainal veneers. These dominate on MP1X tracts. Turbic phases of MP1 soils, produced by solifluction and cryoturbation, are common, particularly on moderately well to imperfectly drained localities with seepage (Plate 138). Physical thickening, rearrangement, mixing, and disruption of upper sola horizons are manifestations of solifluction and cryoturbation processes (Color Plate 43). Regosolic soils are associated with severely soliflucted, cryoturbated, and colluviated localities. Imperfectly drained, Gleyed Brunisolic, Podzolic, and Regosolic soils occur locally on seepage affected sites.

A pedon illustrating Orthic Eutric Brunisols of MP1 is described in Table 253 and shown in Color Plate 44. This profile displays two phases of calcareous, medium textured till (Till C); the lower, darker colored one contains a significant amount of material derived from the underlying Mesozoic strata. The lower till has an abnormally high coarse fragment content that is attributed to its nearness to the source and short distance over which the till materials have been transported by ice.

Vegetation

The vegetation of MP1 is dominated by the mountain avens-snow willow-moss campion (H1) and heather-everlasting (L5) v.t.s. Usually H1 is most abundant, particularly in eastern portions of Banff and Jasper on exposed tracts, on tracts with shallow parent material, and on cryoturbated and soliflucted tracts. The L5 v.t. occurs on more sheltered, stable slopes where snow accumulation is greater. It is dominant on many MP1 tracts of high snowfall areas, e.g. western Banff and Jasper. Important accessory v.t.s are white mountain heather-mountain avens-snow willow (L4) and hairy wild rye-junegrass-bearberry (H14). The L4 v.t. occurs in late snow lie localities. Black alpine sedge-everlasting (H2) occurs occasionally in yet later snowbeds. The H14 v.t. is common on subxeric, steeply sloping localities with southerly aspects, usually on morainal landforms associated with Mesozoic strata in eastern Banff and Jasper. The mountain avens-kobresia-bearberry (H4) v.t. occurs in minor amounts under conditions similar to those for H14 but at higher elevations. Tracts of MP1 and with H14 and H4 usually are bounded below by tracts of Tyrrell 1 or 2 (TR1, TR2). Seepage affected sites have moist v.t.s such as arctic willow-cinquefoil (L7) and fleabane-valerian (H16). Up to 20% krummholz and tree islands are included along lower boundaries of some MP1 tracts. A stand representing vegetation of the pedon sample site described above (Table 253) and illustrating H1 on MP1 is presented in Table 254 and Plate 139.

Discussion

In terms of physiographic position, landform surface expression and vegetation cover, MP1 resembles the Jonas 1 (JN1) and Eiffel 1 (EF1) Ecosites. However, JN1 in contrast to the calcareous Till C of MP1 occurs on morainal landforms consisting of noncalcareous, medium textured till (Till B) and EF1 occurs on noncalcareous, coarse textured till (Till A). Also both JN1 and EF1 are dominated by acidic, well developed soils, including Podzols. Regosolic soils occur less frequently on EF1 and JN1 than on MP1. Mountain avens-snow willow-moss campion

(H1) v.t. is less abundant on JN1 than on MP1. In contrast to MP1, the H1 occurs only occasionally, as an accessory v.t. on EF1. The Peyto Lake 4 (PL4) Ecosite is the Upper Subalpine counterpart of MP1.

MQ - MOSQUITO ECOSECTION

The Mosquito (MQ) Ecosection occurs on fluvial landforms (fans and aprons) comprised primarily of calcareous, coarse, stratified fluvial material (Fluvial material B), occasionally of noncalcareous, coarse, stratified fluvial material (Fluvial material A). It is dominated by Brunisolic and Regosolic soils associated with Engelmann spruce - subalpine fir open and closed forests. Modification by channeling (Eroded modifier, C.S.S.C. 1978b) is a common feature.

The MQ Ecosection occurs on lower slopes and valley floors in the Upper Subalpine portion of the Subalpine Ecoregion in Banff and Jasper.

Only one Ecosite (MQ1) is recognized within the MQ Ecosection. Table 255 outlines the general features of the MQ1 Ecosite.

MQ1 - MOSQUITO 1 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, MQ1, occurs on relatively stable fluvial fans and aprons comprised primarily of calcareous, coarse, stratified fluvial material (Fluvial material B), occasionally of noncalcareous, coarse, stratified fluvial material (Fluvial material A). Modification of these landforms by channeling is common. Well to moderately well drained Orthic and Eluviated Eutric Brunisols and Orthic Regosols dominate the MQ1 Ecosite. Orthic and Eluviated Eutric Brunisols are most abundant. Vegetation is characterized by the Engelmann spruce-subalpine fir/grouseberry (C15), and Engelmann spruce-subalpine fir/heather (O10) v.t.s, with C15 most abundant.

This Ecosite is widely distributed in the Upper Subalpine, but with limited extent in any area.

Geomorphology

The MQ1 Ecosite is characterized by fans and aprons comprised primarily of calcareous, coarse, stratified fluvial material (Fluvial material B), occasionally of noncalcareous, coarse, stratified fluvial material (Fluvial material A). Modification by channeling is common. Surficial veneers of altered, medium textured eolian material (Eolian material B) occur occasionally but are most common on MQ1 tracts located in western Banff and southwestern Jasper. They may also be water reworked eolian material. Other fluvial landforms occasionally found in MQ1 tracts include veneers and terraces. Veneers usually overlie morainal landforms.

Topographically, MQ1 has linear slopes commonly ranging from 5 to 45%.

Soils

The MQ1 Ecosite is dominated by well to moderately well drained Orthic and Eluviated Eutric Brunisols, with fewer tracts dominated by Orthic Regosols. The degree of development of the Brunisolic soils reflects geomorphic stability. The well developed Bm and Bf horizons of these soils are associated with local occurrences of altered, medium textured eolian material (Eolian material B) or water reworked eolian material. Orthic Regosols and minor amounts of Cumulic Regosols occur on entire tracts or near channels that are subject to episodic flooding, or modified by snow avalanching (MQ1A). Orthic Dystric Brunisols occur occasionally and are associated with the few tracts found on noncalcareous, coarse, stratified fluvial material (Fluvial material A). A pedon illustrating Orthic Eutric Brunisols of MQ1 is described in Table 256. This pedon was sampled in Bow Pass in Banff. The buried horizons in this pedon are evidence of historic episodic flooding.

Vegetation

The MQ1 Ecosite is characterized by the Engelmann spruce-subalpine fir/grouseberry (C15) and Engelmann spruce-subalpine fir/heather (O10) v.t.s. The C15 v.t. is most abundant but some tracts are dominated by the O10 v.t. Minor amounts of the Engelmann spruce-subalpine fir/hairy wild rye-heartleaf arnica-twinflower/feathermoss (C31) and Engelmann spruce/hairy wild rye (C33) v.t.s occur on tracts in eastern Banff

and Jasper. The Engelmann spruce-subalpine fir/rock willow/alpine bearberry (O12), Engelmann spruce-subalpine fir/valerian-fleabane (O9), and willow-dwarf birch/fleabane (S4) v.t.s occur in small amounts on tracts that are modified by snow avalanching (MQ1A). A plot illustrating the C15 v.t. of MQ1 is described in Table 257, and represents the vegetation at the pedon sample site described in Table 256.

Discussion

The MQ1 Ecosite is the Upper Subalpine counterpart of the Lower Subalpine Altrude 2 (AL2) and Verdant 1 (VD1) Ecosites.

NG - NIGEL ECOSECTION

The Nigel Ecosection occurs on calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Upper Subalpine portion of the Subalpine Ecoregion. Soils are Eutric Brunisols, and vegetation is moist Engelmann spruce-subalpine fir closed and open forest.

Only two tracts of NG are mapped, both in Banff. One straddles the confluence of Nigel and Hilda Creeks below Sunwapta Pass and the other is on the headwaters of the Red Deer River just below Red Deer Lakes.

Nigel is a valley floor Ecosection. Only one Ecosite is recognized (NG1) with characteristics as outlined in Table 258 and Fig. 45.

NG1 - NIGEL 1 ECOSITE

Ecosite Concept

The NG1 Ecosite is characterized by terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) in the Upper Subalpine portion of the Subalpine Ecoregion. The presence of altered, medium textured eolian material (Eolian material B) and good drainage results in development of Eluviated Eutric Brunisols. Engelmann spruce-subalpine fir/grouseberry (C15) forests and Engelmann spruce-subalpine fir/heather (O10) open forests are the typical vegetation types.

Geomorphology

The NG1 landform is simple, consisting of terraces of calcareous, coarse textured glaciofluvial material (Glaciofluvial material B) deposited during deglaciation. These areas have since remained quite stable and have accumulated a thin mantle of altered, medium textured eolian material (Eolian material B). Both mapped areas are bisected by modern (nonglacial) streams that follow the original glaciofluvial stream channels.

Soils

Long-term landform stability has resulted in Eluviated Eutric Brunisols of uniform development on NG1. A pedon illustrative of these soils is shown in Table 259 and Color Plate 45.

Textures of this pedon are finer than modal for glaciofluvial materials because fissile calcareous shales exert a substantial influence in this tract. Massive bedding and coarse fragment content suggest a depositional environment similar to other glaciofluvial deposits in the parks. Horizon development is typical of stable forested areas on calcareous material throughout Banff and Jasper, including the textural Btj horizon immediately below the eolian-glaciofluvial parent material disconformity.

Drainage on NG1 is consistently good because of rapidly permeable coarse materials and terraced surfaces elevated above the local water table.

Table 258 General features of the Nigel 1 (NG1) Ecosite.

Ecosite	Landform	Soils	Vegetation
NG1	Glaciofluvial material B; terrace	Eutric Brunisol	Engelmann spruce-subalpine fir closed and open forests

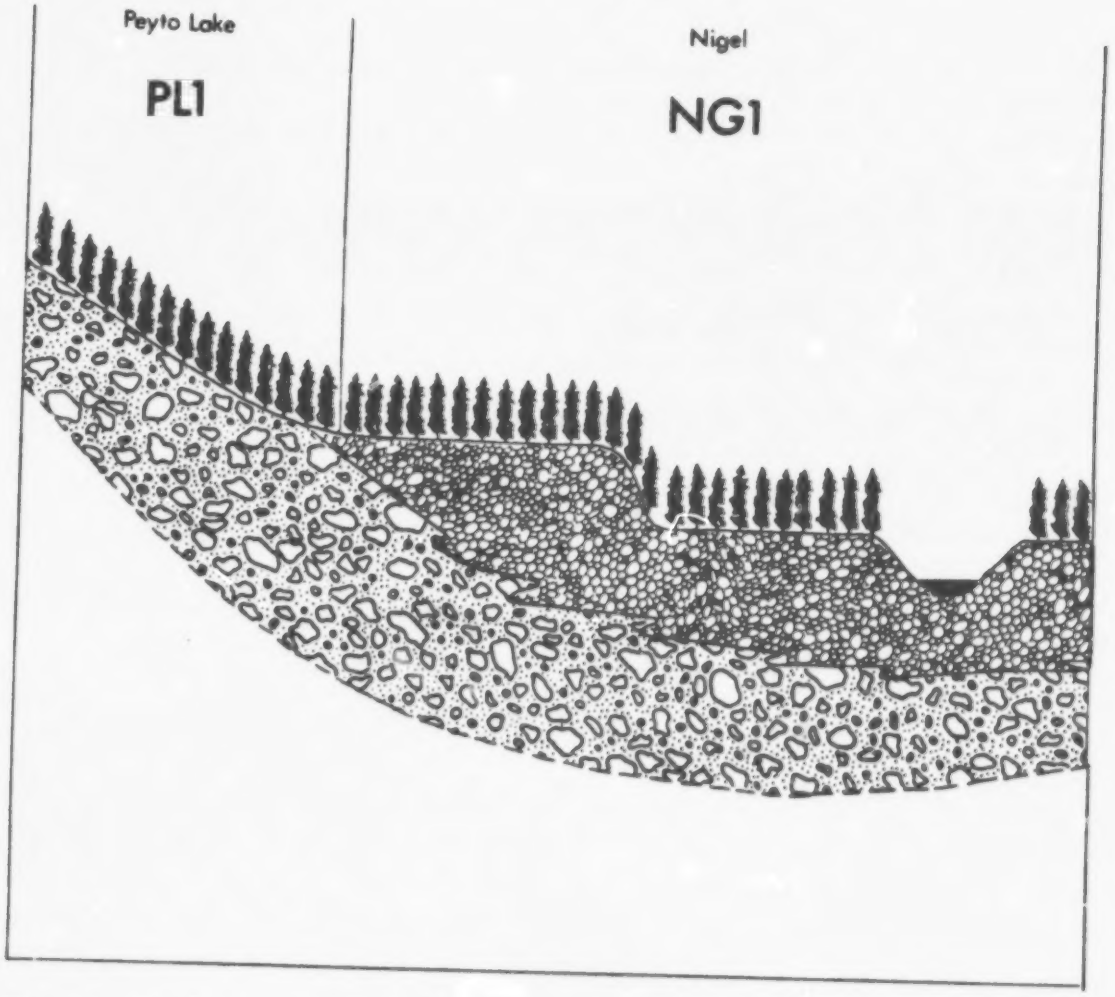
Figure 45 Landscape schematic of the Nigell (NG1) Ecosite.



The only disturbance to soils is infrequent windthrow of trees causing local examples of the turbic phase.

Vegetation

General stability is reflected in the development of uniform Engelmann spruce-subalpine fir/grouseberry (C15) and Engelmann spruce-subalpine fir/heather (O10) v.t.s on NG1. The tract near Red Deer Lakes is consistently C15 as illustrated in Table 260 and shown in Plate 17. This plot was recorded at the same site as the NG1 pedon sample in Table 259.

Near Sunwapta Pass on Nigel Creek NG1 vegetation is best represented by the O10 v.t., but the similar Engelmann spruce-subalpine fir/heather/feathermoss (C34) v.t. also occurs. This tract in the vicinity of the Columbia Icefield is subject to deep snow accumulation and cold air drainage.

Discussion

The two mapped tracts of NG1 are the only known occurrences of landscape with NG1 characteristics. Glaciofluvial deposits are rare at Upper Subalpine elevations, but in both instances an appropriately gentle valley gradient existed in conjunction with a sufficiently large icefield up valley to generate this landform.

Slopes of both tracts are 1 to 15% and complex. While a majority of the land is nearly level, slopes are called complex because of the short steep terrace scarps (Fig. 45).

The Red Deer River tract of NG1 is uniform and undisturbed, while the Nigel Creek one is more heterogeneous and includes both natural and human disturbance. The north end of the latter tract has a small creek depositing a fan of modern fluvial material

over the glaciofluvial landform. This fan is locally wet and has small patches of the willow/cinquefoil (S8) v.t. The south end of this tract borders a steep avalanched slope, and the avalanche run-out zone extends onto the more level glaciofluvial valley bottom. This same area of NG1 also presently contains a warden cabin, its access via the former road through Sunwapta Pass, and the first portion of the trail to Nigel Pass.

The NG Ecosection may resemble the Azure (AZ) Ecosection, but AZ glaciofluvial material is noncalcareous, has more acidic soils, and is found in association with other noncalcareous Ecosites in areas where lime is absent in the surrounding bedrock. The glaciofluvial NG Ecosection resembles Peyto Lake 1 but the till landform and geologic materials of PL1 separate them as shown in Fig 45.

NH - NASHAN ECOSECTION

The Nashan (NH) Ecosection occurs in the Montane Ecoregion and is characterized by blankets of calcareous, fine textured glaciolacustrine material overlying hummocky and undulating slopes of calcareous glacial materials. The NH Ecosection represents a wet and dry landscape pattern. Wet depressional areas comprise about 80% of the landscape and are dominated by Gleysolic soils and open spruce forests. The dry segments of the landscape are dominated by Luvisolic and Brunisolic soils and lodgepole pine forests.

The NH Ecosection is mapped only in Jasper. The majority of NH is mapped on valley floor benchlands above the Rocky River between Dromore Creek and the Athabasca River valley, and in the Snake Indian River valley between Shale Banks and Seldom Inn warden cabins.

The NH Ecosection is represented by only one Ecosite (NH1). The general features of this Ecosite are outlined in Table 261. Fig. 46 shows the position of NH1 on the landscape.

NH1 - NASHAN 1 ECOSITE

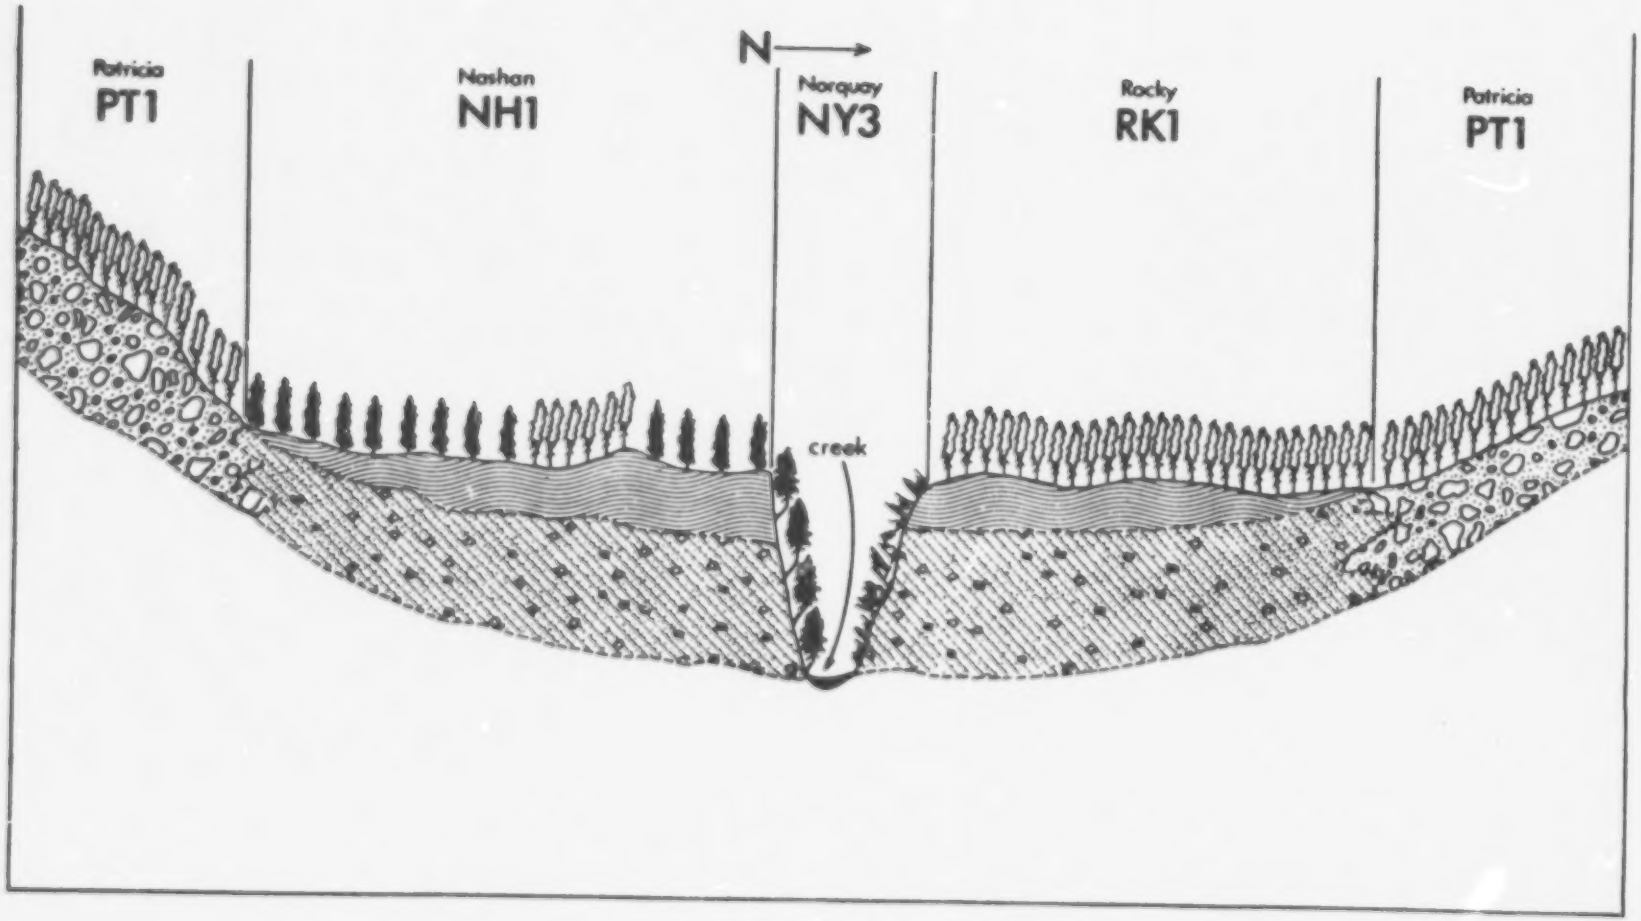
Ecosite Concept

The Montane Ecosite, NH1, represents a wet and dry landscape pattern characterized by blankets of calcareous, fine textured glaciolacustrine material overlying hummocky and un-

Table 261 General features of the Nashan 1 (NH1) Ecosite.

Ecosite	Landform	Soils	Vegetation
NH1	Glaciolacustrine material; blanket	Wet[30]: Gleysolic Dry[30]: Luvisolic, Brunisolic	Wet[30]: spruce open forest Dry[30]: lodgepole pine forest

Figure 46 Landscape schematic showing the relationship of the Nashan 1 (NH1) Ecosite to other Ecosites.



dulating slopes of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). The wetland portion of NH1 dominates about 80% of the landscape and is typified by Orthic and Rego Gleysols associated with the spruce/Labrador tea/brown moss (O11) v.t. On the dry portions of NH1, well to moderately well drained Orthic and Brunisolic Gray Luvisols are more common than Eluviated Eutric Brunisols as the dominant soils and are associated with the lodgepole pine/buffaloberry/twinflower (C19) and lodgepole pine/Labrador tea (C29) v.t.s.

Geomorphology

The NH1 Ecosite is characterized by a wet and dry landscape comprised of blankets of calcareous, fine textured glaciolacustrine material overlying hummocky and undulating slopes of calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B). The glaciolacustrine material in the lower Rocky and Snake Indian River valleys is sediment deposited in proglacial lakes but the cause of damming is unknown. The dominant wet landscape of NH1 usually has thin organic veneers of fen peat and veneers of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A). Seepage and other surface waters accumulate on the landscape. Slow perviousness of the glaciolacustrine material and slow runoff on the gentle slopes results in poorly drained soils and high, possibly perched, water tables. Slopes are commonly complex and range between 0 and 10%. Thin, discontinuous surficial veneers of altered, medium textured eolian material (Eolian material B) can be identified on the dry segments.

Soils

Soils of the NH1 Ecosite are distributed in a pattern governed by drainage conditions. A set of pedogenically related soils occur on the poorly drained segment. They are best represented by Orthic and Rego Gleysols. Many pedons have organic veneers, usually of moderately decomposed fen peat between 15 and 40 cm thick (peaty phase), overlying mineral soil. Terric Mesisols are accessory soils occuring where fen peat is >40cm thick. Other Organic soils with subdominant humic and fibric layers occur. A pedon illustrating Rego Gleysols (peaty phase) on wetland portions of NH1 is described in Table 262 and shown in Color Plate 46.

Orthic and Brunisolic Gray Luvisols are more common than Eluviated Eutric Brunisols as the dominant soils on the dry (well to moderately well drained) segments of NH1. These soils have textural B horizons, many with pedogenic clay film development sufficient to be Bt horizons, occurring at or below the interface between the eolian and glaciolacustrine material. Iron, aluminum, and humus enriched Bm horizons developed in veneers of altered, medium textured eolian material (Eolian material B) veneers overlie the textural B horizons. Orthic Gray Luvisols occur where the veneer is thin or absent. Orthic Eutric Brunisols are accessory soils that occur where the eluvial (Ae) horizons are weakly expressed or absent. A pedon sampled on the dryland portion of NH1 is described in Table 263 and shown in Color Plate 47.

Vegetation

The NH1 Ecosite is dominated by the spruce/Labrador tea/brown moss (O11) v.t. on wet portions of the landscape and, on the dry segments, with the lodgepole pine/buffaloberry/twinflower (C19) and lodgepole pine/Labrador tea (C29) v.t.s. Black spruce-lodgepole pine/willow/sedge (C8) occurs as an accessory v.t. on the wetland portion of the landscape. On tracts of NH1 mapped in the lower Rocky River area *Larix laricina* (tamarack) is commonly found in the O11 and C8 v.t.s. On dry portions of NH1 the lodgepole pine/feathermoss (C11) v.t. may occur.

A stand illustrating the O11 v.t. on the wet portion of NH1 is described in Table 264 and shown in Plate 43. This stand represents the vegetation at the pedon site described in Table 261. The cover of *Carex aquatilis* at this site is higher than in most O11 stands. A stand illustrating the C19 v.t. on dry upland portions of NH1 is described in Table 321 for the RK1 Ecosite.

Discussion

Dry segments of the NH1 Ecosite have the same characteristics as the Rocky 1 (RK1) Ecosite. However, RK1 is only mapped when dry segments are large enough to be delineated at a map scale of 1:50,000. Tracts of RK1 sometimes occur adjacent to those of NH1 on the landscape. Also, NH1 also resembles the Merlin Castle 1 (MC1) Ecosite but the latter occurs in the Lower Subalpine portion of the Subalpine Ecoregion.

A good example of NH1 occurs on a benchland south of Rocky River between Nashan Creek and the Athabasca River valley.

NT - NUM-TI-JAH ECOSECTION

The Num-Ti-Jah Ecosection is complex and encompasses wet fluvial and fluviolacustrine landforms throughout the Upper Subalpine portion of the Subalpine Ecoregion in Banff and Jasper. Gentle slopes on level plains, aprons, and fans are characteristic. These landforms consist of calcareous, coarse, stratified fluvial material (Fluvial material B),

noncalcareous, coarse, stratified fluvial material (Fluvial material A), altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A) and occasionally, calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B). Horizontal fens that thinly mantle the fluvial and fluviolacustrine materials on the wettest localities also occur, particularly on the NT3 Ecosite.

Gleysolic soils lacking pedogenic horizonation characterize the NT Ecosection. Organic soils are also common on the NT3 Ecosite. Shrubby vegetation versus meadow and fen vegetation differentiates the two NT Ecosites. The NT2 Ecosite is dominated by wet and moist shrub thicket, NT3 by wet herb meadow, cottongrass fen and sedge fen. The landform, soil and vegetation differences of the two NT Ecosites are outlined in Table 265.

The NT Ecosection occurs most often on valley and col floors adjacent to streams. High water tables, seepage, and discharge account for its wetness. The NT2 and NT3 Ecosites are shown, schematically, on Figs. 42, 53, and 54. A few tracts occur on broad, gently sloping shoulders and are affected primarily by seepage.

NT2 - NUM-TI-JAH 2 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, NT2, encompasses wet fluvial landforms dominated by shrub vegetation. These landforms consist primarily of calcareous, coarse, stratified fluvial material (Fluvial material B) and noncalcareous, coarse, stratified fluvial material (Fluvial material A). Surface expressions include level floodplains, aprons, and fans. Many surfaces are eroded (channeled).

Imperfectly to poorly drained Rego Gleysols, most with surface peat layers, dominate NT2. These reflect recent parent material deposition, prolonged periods of saturation, and organic material accumulation in stable geomorphic environments. Vegetation is dominated by the willow/cinquefoil (S8), willow-dwarf birch/fleabane (S4), and willow/ timber oatgrass (S11) v.t.s. Of these three, S8 is most abundant.

Geomorphology

The NT2 Ecosite is typified by fluvial landforms consisting of noncalcareous, coarse, stratified fluvial material (Fluvial material A) and calcareous, coarse, stratified fluvial material (Fluvial material B). Weakly calcare-

Table 265 General features of the Num-Ti-Jah (NT) Ecosites.

Ecosite	Landform	Soils	Vegetation
NT2	Fluvial material A,B; level, apron, fan	Gleysolic	wet shrub thicket, moist shrub thicket
NT3	Fluviolacustrine material A,B; level and horizontal fen	Gleysolic, Organic	wet herb meadow, cottongrass fen, sedge fen

ous intergrades between the two fluvial deposits occur often. Important accessory genetic materials, occurring as veneers on or layers within the fluvial deposits, are calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B) and occasionally, altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A). The fluviolacustrine materials occur on what were backwater depositional localities of floodplains and as veneers on the fringes of gently sloping aprons and fans. Organic soils or Gleysolic soils with well developed peat layers are frequently associated with the fluviolacustrine material, both features indicating ponding by currentless, relatively stagnant water. The fluvial and fluviolacustrine deposits may contain reworked material originally deposited as altered, medium textured eolian material (Eolian material B). Glaciofluvial deposits, mainly calcareous, coarse textured glaciofluvial material (Glaciofluvial material B), occur on tracts associated with glacial streams (e.g. Douglas Creek). Various tills underlie the fluvial deposits at shallow depths on some localities. Small morainal outcrops occur sporadically.

Surfaces of NT2 Ecosite soils are usually thinly mantled by peat derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*). This fen peat is dominantly moderately decomposed. The accessory landforms include horizontal fens occurring on ponded localities where organic layers exceed 40 cm in thickness.

Topographically, NT2 displays gentle linear slopes on level floodplains, aprons, and fans. Fluvial blankets overlying till also occur occasionally. Slopes commonly range from 0 to 15% with slopes over 5% encompassing fans and aprons extending from lower valley walls to valley floors. Tracts with complex slopes have irregular surfaces reflecting, in part, underlying morainal landforms. Slope continuity is often broken by abandoned and active stream channels including their natural levee borders (Eroded modifier, C.S.S.C. 1978b). These are most abundant on floodplains. Weakly expressed terracing (risers <1 m) is a minor feature on some floodplain tracts.

Soils

Imperfectly to poorly drained Rego Gleysols dominate the NT2 Ecosite. Prolonged periods of saturation (high water tables or seepage) plus recent sediment deposition have inhibited pedogenic development other than gleization. Thin peat layers occur at the surface on most NT2 soils. Terric Mesisols occur as accessory soils where organic accumulations exceed 40 cm on very poorly drained, ponded sites. These Organic soils are most often associated with minor amounts of v.t.s such as water sedge-beaked sedge (H11) and only occasionally with the dominant shrub types, namely willow/cinquefoil (S8). Gleyed Cumulic Regosols also occur as accessory soils and are associated with imperfectly drained, slightly elevated sites where the upper portions of control sections are weakly gleyed. Organic soils with subdominant humic or fibric layers, Humic Gleysols, Orthic Gleysols, gleyed Brunisolic soils, and gleyed Regosolic soils other than Gleyed Cumulic Regosols occur in minor amounts on wet sites. Well to moderately well drained Brunisolic and Regosolic soils occur sporadically on sites where the fluctuating water table rarely reaches the control section. Soils with disrupted layers occur occasionally, these being affected primarily by cryoturbation.

A pedon illustrating Rego Gleysols of NT2 is described in Table 266. The sample site is shown in Plate 140. This pedon varies slightly from modal NT2 soils. Its lack of surface peat layers reflects the relatively dry surface conditions of the site. It also has an abnormally thick fluviolacustrine veneer.

Vegetation

Vegetation of the NT2 Ecosite is complex and is best represented by the willow/cinquefoil (S8), willow-dwarf birch/fleabane (S4), and willow/timber oatgrass (S11) v.t.s. While S8 is most abundant, some tracts may be dominated by S4 and S11. On NT2, S4 and S11 display a wide range of moisture tolerances, occurring throughout well drained to poorly drained sites. They tend to occur mostly on dry surfaces even though the water table may be near the surface for part of the growing season. Dwarf birch-shrubby cinquefoil-willow/brown moss (S1), water sedge-beaked sedge (H11), and fleabane-valerian (H16) are accessory v.t.s. Occasionally S1 occurs at low to moderate Upper Subalpine elevations, and H11 occurs on ponded localities. H16 is possibly related to high snow accumulation localities. Cottongrass/moss (H10) also occurs in minor amounts on ponded localities, but less frequently than H11. Patches of Engelmann spruce-subalpine fir/valerian-fleabane (O9) v.t. and Engelmann spruce-subalpine fir/rock willow/alpine bearberry (O12) v.t. occur in small amounts. Other v.t.s occurring in minor amounts are mountain marigold-globeflower (H9), arctic willow-cinquefoil (L7), dwarf birch-willow/kobresia (S9), and willow/hairy wild rye (S12). The S9 and S12 v.t.s. favor dry surface conditions and occupy portions of tracts that are transitional to the Cyclone 1 (CN1) Ecosite. Actively aggrading and eroding stream reaches lacking vegetation occupy up to 50% of some tracts. Tracts mapped as NT2+SC (e.g. Douglas Creek in Banff) have 50 to 80% unvegetated portions. Modification of NT2 vegetation by avalanching (NT2A) occurs infrequently.

Discussion

The NT2 Ecosite encompasses wet fluvial terrain dominated by shrubby vegetation in the Upper Subalpine. Vermilion Lakes 5 (VL5) and Hector 4 (HC4) are the Montane and Lower Subalpine counterparts, respectively, of NT2. In particular, HC4 resembles NT2 but has a greater diversity of dominant drainage regimes and vegetation reflecting the Lower Subalpine environment. VL5 has Montane rather than Upper Subalpine vegetation and occurs in active geomorphic environments. In a broad sense, NT2 resembles gently sloping, wet portions of the Alpine Katherine 1 (KA1) Ecosite. However, KA1 occurs mainly on fluvial fans and aprons rather than fluvial and fluviolacustrine landforms and is dominated by meadow and tundra vegetation. The Sphinx 3 (SX3) Ecosite resembles NT2 in terms of vegetation but is characterized by morainal landforms with a greater variety of soils. In terms of landform, NT2 resembles the Cyclone 1 (CN1) Ecosite. However, CN1 has significantly drier soils and vegetation. Wet segments of the Peyto Lake 5 (PL5) and occasionally, Egypt 3 (EG3) Ecosites resemble NT2. These moraine-dominated Ecosites have a compound dry > wet landscape pattern with attendant differences in soil and vegetation. The NT2 Ecosite is differentiated from NT3 by its soils and vegetation (Table 265) reflecting a slightly different geomorphic history.

NT3 - NUM-TI-JAH 3 ECOSITE

Ecosite Concept

The Upper Subalpine Ecosite, NT3, encompasses ponded, fluviolacustrine, backwater floodplains dominated by meadow and fen vegetation. This landform consists primarily of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A), and occasionally of calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B). Sediment loads of inundating waters are low and promote the accumulation of organic materials. Horizontal fens that thinly mantle the fluviolacustrine deposits occur frequently. The floodplain surfaces are usually eroded (channeled) with slightly elevated, gently sloping levees bordering the channels. Pools, ponds, and small lakes occur sporadically on NT3.

The poorly to very poorly drained soils of NT3 reflect, in their development, the degree of ponding and amount of peat accumulation. Rego Gleysols and Terric Mesisols are dominant with the Rego Gleysols being more abundant. Vegetation of NT3 reflects degree of ponding and elevation and is dominated by the mountain marigold-globeflower (H9), cottongrass/moss (H10), and water sedge-beaked sedge (H11) v.t.s.

The NT3 Ecosite is primarily associated with high snowfall areas that are dominated by Gog Group quartzites and Miette Group slates and shales. Consequently, it is most abundant along the Continental Divide, particularly in northwestern Jasper, north and west of the Athabasca River, Snaring River, and Blue Creek valleys.

Geomorphology

The NT3 Ecosite is typified by level fluviolacustrine floodplains consisting primarily of altered, fine, stratified fluviolacustrine material (Fluviolacustrine material A), and less often of calcareous, fine, stratified fluviolacustrine material (Fluviolacustrine material B). Fluvial deposits, mainly noncalcareous, coarse, stratified fluvial material (Fluvial material A), also occur occasionally at the mineral surface and probably underlie the fluviolacustrine deposits. At undetermined depths, on some tracts, fluviolacustrine deposits are probably underlain by till, mainly noncalcareous, medium textured till (Till B). The fluviolacustrine materials were deposited by siltation from silt-laden glacial meltwaters ponded on backwater floodplains. These floodplains were created by downstream constriction of major drainage channels. The ponded basins also received, from surrounding slopes, slope-wash material deposited along their margins. Although ponding is still extensive on NT3, sediment deposition is minor due to the low

sediment loads of inundating waters. Recent and present conditions favor organic material accumulation under well developed moss layers. Consequently, most NT3 soils have thin peat layers at the surface. This peat is derived primarily from sedges and brown mosses (e.g. *Tomenthypnum nitens* and *Aulacomnium palustre*) and rarely exceeds 1.2 m in thickness. Moderate decomposition is characteristic but fibric and humic layers also occur. Where the peat is >40 cm thick, the landform is classified as horizontal fen (C.S.S.C. 1978b). Horizontal fens dominate some NT3 tracts (e.g. the valley floor below Grant Pass in Jasper). Mineral and organic layers are occasionally interbedded.

Topographically, NT3 displays gentle linear slopes on level to gently concave or bowl-shaped floodplains. Slopes commonly range from 0 to 3% with steeper gradients marking tract fringes to surrounding, steeper sloping landscape. Slope continuity is broken by numerous abandoned and active stream channels meandering across the landscape (Eroded modifier, C.S.S.C. 1978b). Gently sloping, slightly elevated levees often border the channels. Excepting the levees and tract margins, NT3 is usually inundated for much of the summer season. Pools, ponds, and small lakes occur sporadically on the landscape.

Soils

The NT3 Ecosite is dominated by Rego Gleysols and Terric Mesisols with the Rego Gleysols being most abundant. Some tracts, however, are dominated by Terric Mesisols (e.g. below Grant Pass). These poorly to very poorly drained soils are subjected to prolonged periods of saturation that promote strong gleying but inhibit pedogenic horizonation. Recent and present geomorphic environments favor fen peat accumulation on soil surfaces. Consequently, NT3 soils have variable thicknesses of surface organic horizons composed predominantly of moderately decomposed fen peat. Terric Mesisols occur where peat accumulations exceed 40 cm. Organic soils with subdominant humic or fibric layers may also occur. Other soils occurring in minor amounts are Humic Gleysols, gleyed Brunisolic soils, and gleyed Regosolic soils. Soils with disrupted layers occur sporadically, these being affected primarily by cryoturbation. A pedon illustrating Terric Mesisols of NT3 is described in Table 268 and shown in Color Plate 48.

Vegetation

Vegetation of the NT3 Ecosite is dominated by the mountain marigold-globeflower (H9), cottongrass/moss (H10), and water sedge-beaked sedge (H11) v.t.s. Distribution of these types is related to elevation and degree of ponding. The H9 v.t. occurs in poorly drained, non-ponded localities including tract fringes and elevated levees. Both H10 and H11 are associated with ponding but H10 is more abundant at higher elevations. Willow/cinquefoil (S8) and fleabane-valerian (H16) are important accessory v.t.s occurring on imperfectly to poorly drained levees and tract fringes. A plot representing vegetation of the pedon sample site (Table 268) and illustrating H11 on NT3 is presented in Table 269 and Plate 141. This H11 plot differs from modal by its high shrub content and H10 tendencies.

Discussion

The NT3 Ecosite is the least extensive of the NT Ecosites and is of low areal extent. It encompasses wet backwater floodplains dominated by meadow and fen vegetation. The NT3 Ecosite resembles the Vermilion Lakes 1 (VL1) and Hector 2 (HC2) Ecosites which are its Montane and Lower Subalpine counterparts, respectively. However, both VL1 and HC2 occur on calcareous fluviolacustrine floodplains rather than the generally noncalcareous floodplains of NT3. Also, most HC2 and several VL1 tracts are presently experiencing sediment deposition whereas NT3 is geomorphically stable. Soils and vegetation reflect these differing geomorphic environments and the different Ecoregions and subdivisions thereof. In general terms, the Sphinx 1 (SX1) Ecosite sometimes resembles NT3 but is characterized by a broad range of imperfectly to poorly drained soils on morainal rather than fluvial landforms. Vegetation reflects the landform and drainage differences. The NT3 Ecosite is differentiated from NT2 by its soil and vegetation (Table 265) reflecting a slightly different geomorphic history.

NY - NORQUAY ECOSECTION

The Norquay Ecosection is characterized by calcareous, medium textured till (Till C) and calcareous, variably textured ice contact stratified drift (Ice Contact Stratified Drift B) in the Montane Ecoregion. Brunisolic and Regosolic soils are found in patterns on the landscape as are lodgepole pine forest, Douglas fir forest, white spruce-Douglas fir forest, open forests of Douglas fir, and low shrub-herb meadows.

This Ecosection is widely distributed throughout the Montane, often bordering rivers and on lower valley wall positions. In Banff, NY ranges from the east gate to Johnston Creek in the Bow River valley, and along the lower North Saskatchewan and Howse Rivers in those locations where eolian material is not actively accumulating over ice contact materials. In Jasper, NY is mapped in the Athabasca River valley and its major tributaries from the east gate to Mount Kerkeslin. This includes the Miette River valley to the west gate, and lower portions of the Fiddle, Rocky, Snake Indian, Snaring, Maligne, and Whirlpool Rivers, and wider creek valleys such as Moosehorn and Jacques.

Two Ecosites (NY1, NY3) are recognized within the NY Ecosection. Table 270 lists the essential characteristics of each Ecosite. A representation of NY Ecosites on the landscape is presented in Fig. 47.

NY1 - NORQUAY 1 ECOSITE

Ecosite Concept

The Norquay 1 Ecosite is characterized by blankets and veneers of calcareous, medium textured till (Till C) over inclined bedrock in the Montane Ecoregion. Orthic Eutric Brunisols form a pattern with less frequently encountered Orthic Regosols on rapidly to well drained slopes, and is forested with either Douglas fir/hairy wild rye (C1) or lodgepole pine/buffaloberry/showy aster (C6) v.t.s. It is found throughout the Montane on steeper (30-70%) grades. The linear inclined form of NY1 landforms is considered depositional (cf NY3, and Fig. 47).

Geomorphology

Modally, NY1 landforms are composed of blankets and veneers, often gullied, of calcareous, medium textured till (Till C) over inclined bedrock. While surfaces may be modified by gully erosion or shallow surface colluviation, especially on south aspects, inclined surficial expression is controlled by the ice depositional medium and the surrounding bedrock. Although NY1 tracts are often in areas where altered, medium textured eolian material (Eolian material B) is abundant, its presence or absence at any given location depends on local surface stability. Small fluvial fans and aprons are common at the base of gullied NY1 slopes. Bedrock also may be exposed where original morainal deposition was thin.

In the Miette River valley in Jasper, NY1 is mapped on areas of noncalcareous, medium textured till (Till B). The absence of lime is controlled by the extensive Miette Group strata in the surrounding area.

Soils

Soils on NY1 are strongly influenced by present and historical local surface stability on the inclined slopes. The landscape pattern is dominated by Orthic Eutric Brunisols with a lesser percentage of Orthic Regosols. Both soils reflect the quasi-equilibrium of the ground surfaces of this Ecosite. Erosion is gradually removing the surface layer at a rate just slower than pedogenic processes are operating to produce horizon differentiation. The Orthic Regosols frequently have Bm horizons, but <5 cm thick, indicating they are similar to the Orthic Eutric Brunisols in genesis. This pattern is more evident on steeper southerly aspects where exposure, through mechanisms such as greater frequency of fire and less vegetation cover, results in bare mineral soil that is subject to erosion. Northerly aspects display more uniform Brunisolic development because of less extreme exposure. Most stable locations on this aspect have Eluviated Eutric Brunisols associated with altered, medium textured eolian material. Table 271 and Color Plate 49 are informa-

Table 270 General features of the Norquay (NY) Ecosites.

Ecosite	Landform	Soils	Vegetation
NY1	Till C; blanket, veneer	Eutric Brunisol > Regosolic	lodgepole pine forest, Douglas fir forest
NY3	Ice Contact Stratified Drift B; inclined, hummocky	Northerly: Eutric Brunisol Southerly: Regosolic	Northerly: white spruce-Douglas fir forest, lodgepole pine forest Southerly: Douglas fir open and closed forests, low shrub-herb meadow

tion from a pedon chosen to illustrate the soils of NY1. This profile has a thin discontinuous Ae horizon typical of many NY1 soils and a textural luvisolic tendency in the Btj horizon that is frequently observed in Eutric Brunisols in Banff and Jasper. Lithic phases of soils occur on morainal veneers and frequently in a mosaic with rock outcrops. Soils are rapidly to well drained, and seepage, especially on south aspects, is seldom present. Dystric Brunisols dominate NY1 on noncalcareous, medium textured till along the Miette River in Jasper.

Vegetation

The NY1 Ecosite is forested with Douglas fir/hairy wild rye (C1) and lodgepole pine/buffaloberry/showy aster (C6) v.t.s. Vegetation type distribution is influenced by site moisture regime. Stands of C1 are older, successionally mature communities on drier sites, while C6 represents an intermediate to advanced successional stage on moister sites. Table 272 illustrates NY1 vegetation and was sampled at the same site as the NY1 pedon described in Table 271. This C6 stand demonstrates the dry nature of NY1 vegetation even on a moderately exposed east aspect since elements of the more xeric lodgepole pine/juniper/bearberry (C3) v.t. and much Douglas fir are present. More xeric phases of v.t.s often occur with appreciable areas of exposed, erodable mineral soil. Other lodgepole pine/buffalo berry v.t.s such as lodgepole pine/buffaloberry/twinflower (C19) may be expected in NY1, and on more mesic and stable northerly aspects white spruce-Douglas fir/feathermoss (C5) occurs. Douglas fir v.t.s often correlate with shallow to bedrock materials. Minor amounts of v.t.s lodgepole pine/green alder/feathermoss (C10) and lodgepole pine/feathermoss (C11) are present on north aspects on noncalcareous, medium textured till (Till B) mapped as NY1 along the Miette River in Jasper.

Discussion

Evidence of logging still exists on several of the more accessible NY1 tracts. Small patches of grassland are found on steep southerly aspects, most often asociated with Mesozoic aged bedrock. For example Richardson needlegrass-junegrass-everlasting (H13) occurs on the tract containing the road to Mount Norquay ski area in Banff. In Jasper, NY1 mapped in the lower Athabasca and its tributary valleys locally contains Regosolic soils and white spruce vegetation types typical of Talbot (TA3) where the calcareous, medium textured eolian material (Eolian material A) is actively accumulating.

Tracts of NY1+R are mapped frequently on very steep slopes, and often these tracts contain considerable areas of colluvium.
